The greater part of the mercury had been distilled at 270 deg., the temperature being increased proportionately with the pressure of the gas in the apparatus. In order to be able to observe the contents of the boat during the operation, gas heating was employed. At a temperature of 400 deg. the amalgam was solid, but melted as the temperature increased, the mercury being driven off. The melting point could be determined very accurately, as it increased progressively until it reached 700 deg. At this temperature it was no longer possible to see the distillation of the mercury, no condensation being produced on the cold surface. On the contrary, the metal began to volatilise in great abundance, and the vapour energetically attacked the quartz tube, so that the operation was then stopped. This metal seemed to be fairly pure radium. It adhered closely to iron and could not be easily detached.

The metal radium alters very rapidly in air, it blackens immediately, probably owing to the formation of a nitrate. Some particles of the metal were detached, and falling on paper caused a blackening like burning. When brought into contact with water the metal decomposed with violence, most of it dissolving, thus indicating that its oxide is soluble. There remained a blackish residue, which was almost wholly dissolved by hydrochloric acid. This residue might be a nitrate, resulting from the exposure to the air. As dissolution in the dilute acid was almost complete, mercury could not have been present in any appreciable quantity.

The boat with the metal in it was closed up in a tube, which was evacuated in order that the penetration of the radiation might be measured. Its properties seemed to be such as would be supposed.

Radio-active equilibrium has not yet been reached, but the first measurements show that the increase in activity follows closely the law of production of emanation, and the radio-active limit of the metal should be practically normal.

Metallic radium being much more volatile than barium, it is proposed to purify it by sublimation on to a plate of cooled metal in vacuo.

ELECTRIC POWER IN AN OIL MINE.

On Saturday, 10th inst., the annual excursion of the Mining Institute of Scotland took place to Broxburn where the members were the guests of the Broxburn Oil Co. During the day a visit was paid to the New Dunnet mine, in which an electrical installation has just been completed. This interesting installation was described in a Paper read by Mr. W. Clark, of the Broxburn Oil Co., who mentioned that the mines, which are situated about a quarter of a mile north-east of Broxburn village, are only 160 yds. distant from the shale breakers and retorts. The motive power chiefly employed is electricity, obtained from a power station placed alongside the works boilers and within a few yards of the retorts in which all the exhaust steam from the engines is utilised. The steam, instead of being supplied direct to the retorts, first passes through the engines, thus saving fuel.

The generating plant at present consists of a Belliss & Morcom engine, working at a boiler pressure of 90 lb. per square inch, with 1 lb. back pressure, for forcing the exhaust steam into the retorts for the production of ammonia water. The engine is coupled to a Siemens three-phase alternator, which furnishes current at 525 volts and 50 cycles, giving 470 k.v.a. at 300 revs. per min. There is a direct-current exciter on the engine shaft of a capacity of 245 amperes at 110 volts. This exciter gives more current than is required for the machines, and the surplus is used to supply the various lamps in the works during the day. The power station building is constructed to hold two more 575 H.P. generating sets.

The alternating current is delivered to a remote-control switchboard. All the panels are fitted with oil switches, and the high-tension connections are in white brick cells. Current is distributed to the various points by paper-insulated armoured cables. One panel of the switchboard supplies current to a 185 H.P. Siemens-Sulzer pump, a 50 H.P. motor-generator for electric drills, a 150 H.P. double drum haulage, a 25 H.P. dook pump and a 7 H.P. hutch creeper. The Dunnet mine endless rope haulage gear is driven through belts by two motors, each of 110 H.P. and controlled by oil switches, each with a maximum cut-out time relay and no-volt release. This no-volt release is so arranged as to stop the motors automatically in case of runaway hutches, and by push buttons from various convenient points in the mine. The breaker panel supplies a 110 H.P. motor for driving the shale breakers, a 50 H.P.

Digitized by Google

endless rope haulage motor for filling a 2,000-ton bunker with broken shale, and one 25 H.P. motor for hauling shale from the Stewartfield mine to the breakers, and from the Dunnet mine main haulage to the breakers. All the motors for this work are of the slip-ring type, with liquid starters, except the motors driving the high-speed turbine pumps, which are squirrel-cage wound, with star-delta starting arrangement. The lighting of the works is provided for by a 75 H.P. Belliss-Siemens set giving 455 amperes at 110 volts and 525 revs. per min.

There is one earth 'bus bar in the power house connected by cable to an earthing plate, which is laid in clay, and also to the earth plates of two adjoining chimneys. All earth connections to the various switches, motors and starters, &c., are made on to the armouring of one or other of the main cables, and these are in their turn connected to the common earth bar in the power station.

The permanent pumping plant consists of a Sulzer high-lift centrifugal pump, direct coupled to a Siemens-Schuckert electric star-delta motor of 185 B.H.P. running at 1,470 revs. per min. when supplied with alternating current of 525 volts and 50 periods. The combined set is capable of pumping 400 gallons of water per minute to a head of 780 ft., plus the friction of 1.740 ft. of 7 in. pipes and 10 ft. for suction lift. The guaranteed efficiency of the pump is 70 per cent. and of the motor 92½ per cent. A small sinking pump of the same type, capable of delivering 150 gallons per minute against a head of 210 ft., has been provided to deal with the dook water below the main lodgment.

The author, towards the close of his Paper, mentioned that a motor-generator was being installed capable of supplying power to 10 Jeffrey electric drills to be utilised for boring shot-holes in the shale.

STREET LIGHTING IN LONDON.

Owing to numerous inquiries received, and in the interest of supply undertakers generally, the Electric Supply Publicity Committee have sent the following letter (of which we have received a copy from Mr. H. B. Renwick, chairman of the Committee) to all the principal papers throughout the country.

LIGHTING OF LONDON.

A most misleading impression has recently been created by certain paragraphs appearing in the press under the above heading. The impression given was that London, instead of continuing an electrically lighted city, as at present, was about to revert to gas. I need hardly say that nothing is further from the truth. The case, however, presents an interesting example of how easily an erroneous impression can be set afloat. The facts are as follows:

One of the 29 London authorities, influenced by conditions which were purely local, decided to alter a few of their numerous electric lamps to gas lighting. The number of the lamps involved is quite small compared with the total number of lamps in the borough in question, and is altogether negligible in comparison with the total electric lighting of London. The whole case, in fact, is simply a local matter, confined to one authority only, and is quite undeserving of the wide publicity, were it not for these incorrect rumours, which have given rise to so much misunderstanding.

For corroboration of the facts, reference need only be made to the official statistics of the London County Council, where it will be seen that the use of electric street lighting has more than doubled in half-a-dozen years, and that only 10 out of the 29 London authorities are wholly without electric street lighting.

As to the relative cost of electricity versus gas for street lighting, I need only mention that in St. Marylebone the saving effected last year was £1,500 in respect of a portion of their area only, and that this has encouraged them to convert the whole of the remaining gas lamps to electric light, which will bring the saving up to £2,600 per annum.

Further, the Boroughs of Hampstead and Shoreditch—already extensively electrically lighted—are extending electric lamps practically throughout the whole of their areas.

REINFORCED CONCRETE FOR CHIMNEY CONSTRUCTION.*

BY P. S. SHEARDOWN.

The two chimneys at the Ringsend power station were built in 1898; they are each 200 ft. above the brick bases, which are themselves 25 ft. high. The stacks above the bases are constructed of steel plates, the bottom 50 ft. being $\frac{3}{8}$ in. thick, the next 50 ft. are $\frac{5}{16}$ in. thickness, and for the top 100 ft. the plates are $\frac{1}{4}$ in. thick. They are lined to the top with fire brick, but as it was anticipated, owing to the height of the chimney, that trouble might be experienced through unequal expansion if the brick work was set hard against the steel work, the linings were built independently, leaving a space of about 3 in. between the brickwork and the steel shell. The chimneys for some years appeared to be doing well, but as a case was brought to the writer's notice of a small works in Dublin where a steel chimney had to be replaced after a life of four or five years, a second one at the same works only giving a similar life to the first, it was considered desirable to make a careful examination of the tramway company's chimneys, more particularly in view of the fact that an inspection of the small chimneys referred to showed that the corrosion of the plates seemed to take place from the inside. As they were not provided with brick linings, like the tramway company's chimneys, corrosion from the inside was not anticipated in these latter. However, when a careful inspection came to be made, it was found that in the case of the east chimney the plates had rusted away until perforation had occurred in several of the plates, corrosion taking place entirely from the inside. The exterior of the plates was well protected by paint, and no deterioration had been noticed at the previous painting of the chimneys. The plates in each chimney were carefully tested by drilling holes and callipering for thickness, when it was found that in many parts of both chimneys the plates had rusted away to an extent that materially reduced their strength, and it was obvious that some method of strengthening them and preventing further corrosion would have to be taken in hand. After carefully considering various methods suggested, it was decided to reinforce both the chimneys with a ferro concrete lining. In the case of the east chmney, which has a diameter at the base of 10 ft. 8 in., it was decided to build a ferro concrete lining 10 in. thick inside the existing brickwork, reducing the diameter of the chimney to 9 ft. It was decided to remove only the top 20 ft. of the original brick lining, so as to get a bond for this length between the ferro concrete lining and the steelwork, in order to prevent deleterious gases or damp from getting between the brickwork and the steel shell. It was intended also to fill in the space between the steel shell and the original brick lining with a liquid cement grouting, but this was not found to be practicable as explained later on.

The lining was designed by the Weber Chimney Construction Co., of U.S.A., and the work was carried out by their licensees, Messrs. J. Jarvis & Sons. The concrete mixture consisted of three parts of fine sand to one part of cement; the vertical reinforcements consisted of steel tee bars 1¼ in. by 1¼ in. by $\frac{3}{16}$ in., and the horizontal reinforcements of $\frac{5}{8}$ in. round steel. These horizontal rings were put in 18 in. apart, the number of vertical steel bars being 300 at the base of the chimney, the number being gradually diminished until at the top there were only 12. The lining is designed to withstand a wind pressure of 56 lb. per square foot (or a velocity of 112 miles per hour) without help from the original steel shell.

The lining of the first chimney was completed in January, 1909, and has been repeatedly inspected from the inside since being put to work, and, so far, the lining seems to stand the heat and other stresses splendidly, as, beyond some small hair cracks, which are always noticeable in this class of construction, the lining is in excellent condition. A couple of months after being put to work it was noticed that the rivets had pulled out of a horizontal section of the steel chimney about half way up, and that the top half had risen about ¾ in. This was caused by the greater expansion of the ferro concrete lining due to its higher temperature compared with the steel shell. The steel shell is, therefore, now in practically two pieces, the overlapping where the rivets have pulled out acting as an expansion joint, the ferro concrete lining, therefore, taking the whole of the wind pressure.

When the proposed grouting between the steel shell and the original brickwork lining was put in hand, it was found that, owing to the quantity of soot that had fallen down between the brickwork

* Some notes (slightly abbreviated) on the reinforced concrete lining of the steel chimney shafts at Ringsend generating station of the Dublin United Tramways Co., and on reinforced concrete for chimney construction. Presented at the Dublin congress of the Tramways and Light Railways Association.

Digitized by Google

and lining, a satisfactory job could not be made, and in consequence of this the west chimney, in which the plates were not so much corroded, was differently treated, the whole of the original brick lining being removed and the ferro concrete lining filled in hard against the steelwork, which enabled the Company to have a chimney with an inside diameter of 10 ft. in place of only 9 ft., as is the case with the east chimney, besides allowing a much greater thickness of concrete in the lower part of the chimney stack. The west chimney has been at work since the beginning of March, and so far with satisfactory results, having been inspected once since it was put to work. The writer is not aware, however, of any case similar to this where a ferro concrete stack has been built inside an existing steel one. The alternative that faced the Company in this case was completely to remove the steel stacks, and build brick or entirely new ferro concrete ones in their place, which would have cost two or three times what the ferro concrete lining cost, without being any more durable or efficient.

Reinforced concrete has been largely used in America for chimney construction, and in the case of tall chimneys this form of construction comes out much cheaper than for brickwork. There have been a number of failures, but it appears that they were all due to the neglect of some of the now well-known conditions which are necessary to insure satisfactory results with all types of ferro concrete construction. The usual practice in chimney construction is to use a mixture of one part of high-class cement to three parts fine clean sharp sand. The sand should be free from any fine silt, and from the fact of it being fine sand requires more careful mixing than where a coarser mixture is used, and for the same reason the sand should preferably be fairly dry when first mixed with the cement, then turned over at least three times when it is being moistened. In order to get a good bond between the concrete and the steel reinforcements, it is absolutely necessary that the concrete should be put in wet, as the failure of several chimneys have been due to the fact that the mixture was put in dry, the result being that the concrete did not adhere to the steelwork, and also formed a weak porous concrete.

With regard to the design of concrete chimneys (independent of outside steel casing) this differs from the design of brick chimneys, due to the fact that the stresses are met in quite a different way. A brick chimney stands because of its weight, the outside diameter of the base being made so large that it cannot blow over, the stresses in the brickwork being entirely compressive. A reinforced concrete chimney is of much smaller size at the base, and would topple over it if could not sustain a tensile strain. A ferro concrete chimney may, therefore, be treated as a beam fixed at one end and loaded on the side on which the wind is blowing, this side being in tension and the opposite side in compression; therefore, the steel reinforcement should be designed to withstand the maximum tensile stresses that are likely to occur. It is customary to assume a pressure of 50 lb. per square foot of vertical surface, which corresponds to a wind pressure of 100 miles per hour. It is, therefore, necessary to have a proper number of vertical steel rods or bars all round the chimney to resist the pull caused by the wind pressure, and steel hoops must also be placed at intervals to stiffen the vertical steel, and prevent cracks due to difference in temperature between the interior and exterior, and especially to resist the vertical shear which corresponds to the horizontal shear in a beam.

With regard to the effect of exceedingly high temperatures on concrete, there seems to be hardly enough experimental data to decide what effect these will have on concrete after long periods of time, but temperatures up to 700 or 800 F. do concrete no harm; in fact, concrete that has been subjected to such temperatures seems to set particularly hard, and as the boiler gases in most stations are usually nearer 500 F., no trouble should be anticipated from this cause, provided the chimney is properly designed. As concrete is a bad conductor of heat, the two or three inches next the surface exposed to the heat of the gases tend to expand to a greater extent than the outer surface, consequently it is not unusual to find small cracks on the outside of concrete chimneys due to this cause. This may be to a certain extent overcome by placing the horizontal reinforcements nearer to the outer surface, but these small cracks are not considered of any consequence, provided they do not run into one another for any great distance. A large number of chimneys are built with a special lining for a third of the height from the bottom of the chimney, the object in view being to overcome this unequal expansion between the inner and outer surfaces, but care has to be taken to strengthen up the reinforcement at the point where the double wall becomes a single one, otherwise cracks are likely to occur.

The method of constructing a new ferro concrete chimney is very simple. Two sets of inner and outer moulds are employed which are connected together by means of latches, enabling the moulds to be easily taken to pieces; after the first two sets of moulds, which correspond to the first two courses of concrete, have been filled in, the lower moulds are taken away and placed on the top of the moulds that were above them, the frictional resistance between the concrete and these upper moulds being sufficient to hold the weight of the next course. As soon as this is set the then bottom set of moulds are taken away and placed on top again, arrangements being made to do this as the construction proceeds from the inside of the chimney, hence no scaffolding is required, except a light scaffolding as the chimney goes up to allow a rough ladder to be erected and sufficient to support the gear for hoisting the material.

ELECTRICITY FOR FARM WORK AND IRRIGATION.*

BY H. RUSSELL.

The Rochester Railway & Light Co. supplies Rochester, N.Y. (200,000 pop.) with electric light and power. The electric development of the Company is both steam and hydraulic, supplemented by a purchase of Niagara power. It has generating apparatus for the production of 38,000 H.P., and the necessary equipment to distribute this. From April 1st to October 1st of every year 10,000 H.P. lies idle (representing an investment of £500,000). This represents the amount necessary to take care of the heavy peak loads in November, December and January. During these months, from 10 p.m. to 6 a.m. there is 10,000 H.P. waiting for a consumer.

The conditions as outlined above are true of every service company in the United States, and it is probably a conservative statement that during these months 40 per cent. of the plant capacity is producing no revenue, and that 75 per cent. is non-productive during six hours of every 24. The problem that confronts the companies is to find a market for this power during these months; in other words, a summer customer, who stays off the peak both daily and seasonly. In searching the field for a possible consumer of this character, the attention of the Rochester Company was attracted to the growing use of power on the farms, and especially to the increased use of power for irrigation pumping in the West, and the very attractive load features that this business offers. The question at once arose, "Is there not a market for this power in rural sections, and should not irrigation be practised by the farmers of the East as well as of the West? If so, can we not extend our lines into the country and sell the power now idle for irrigation pumping at special rates, and incidentally secure much additional farm business?"

The modern farmer wants electric power on his farm, and he is willing to pay for it. That this is the case is shown by the increased use of electricity in rural districts. Here and there all over this country (in New York, Illinois, California, Colorado, and in fact in almost every State) are to be found farms partially or completely equipped with electric power. The reasons for this wonderful growth of electric use on the farm are not hard to find or difficult to understand. The improvement in country roads, the growth of the automobile, the extension of the telephone and rural delivery service, have brought the city and the country closer and closer together, with the result that a farmer and his family are no longer an isolated set of individuals, out of touch with the world and modern progress.

Electric light means comfort in the farmhouse and a lessening of the fire hazard. By providing suitably lighted buildings, work can be done more efficiently; that is, more work and fewer hours. Electric power with its factors of safety, reliability, cleanliness, flexibility and ease of application is peculiarly adapted to pumping water, driving conveyors, running churns, separators, feed cutters, milking machines and grinders; to operating hoists, spraying machines, saws and machine tools; even to doing the household washing and ironing and providing a cold-storage plant. For these purposes, and many more, electric power is now used on the farms of the country. In Europe, where much greater progress has been made than in this country, ploughing, cultivating, &c., are being done with the aid of electricity

At present most of the electric service on the farm is being supplied by the farmer himself, the gasoline, steam or suction-gas plant usually furnishing the motive power, with an occasional hydro-electric private development. A beautiful example of the latter is to be found on the farm of Mr. W. H. Miner, at Chazy, N.Y. Two streams have been dammed and hydro-electric equipment of 192 kw. capacity with storage battery has been installed; transmission lines are 1¼ and 2¾ miles long. There is also a small steam reserve unit operated in connection with the heating system. There are 25 motors aggregating 123½ H.P., doing the farm work at the present time. Three years' operation has proved the efficiency and economy of the undertaking.

* Abstract from "Engineering News" of a Paper read before the National Electric Light Association.

Digitized by Google

The use of gasoline engines for driving small generators, which in turn are used to charge storage batteries supplying electric light, is becoming very common. The advent of the tungsten lamp has aided materially in making this development possible. Manufacturers of farm machinery have taken up the subject, and the makers of electrical machinery are paying especial attention to the rural field.

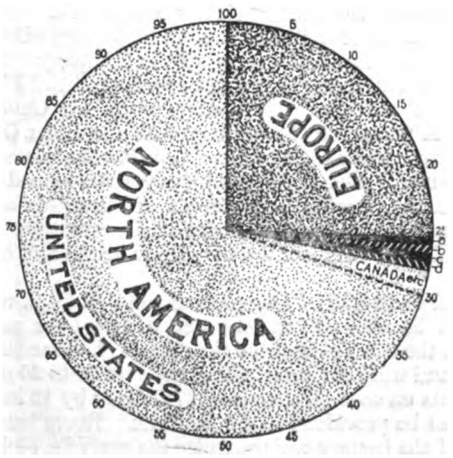
Recently there has sprung up in many sections, especially in the Western States, a demand for power on the farms, which is so large and the nature of which is so atractive from a load standpoint, that it promises to justify for its satisfaction a very large expenditure on the part of service companies. I refer to the use of electric power for pumping water for irrigation purposes. All over the West water is being pumped electrically from wells, rivers, lakes and ditches for irrigation use. Large Government and private company undertakings are now supplying water in this way for thousands of acres. Individual farmers, wherever electric power can be obtained, are installing pumping outfits and irrigating their own land, thereby saving the cost of water rights and maintenance charges, while obtaining water at a very reasonable cost when they want it and where they want it—a condition not always reached with gravity systems.

The electric development for irrigation pumping is proceeding in two ways: (1) A large pumping plant suitably located is installed, and all the water for a given acreage is pumped at this point to a higher level and then distributed by gravity—the power used being electric, with either steam or hydraulic generation; or (2) electric power is furnished from a central plant to the individual farmers, who supply their own water, either from streams, wells, gravity ditches or lakes, as the case may be. The irrigating pumping load is especially attractive to a central station, because it means a large power consumer who is strictly an off-peak customer. Power is used entirely during the summer months, and by special rates is in many cases used during hours of the day when there is almost no other load.

The considerations outlined above have caused the Rochester Railway & Light Co. to inaugurate a novel new business campaign. The writer has been delegated to give special attention to the subject of irrigation for the purpose of demonstrating to the farmers around about Rochester that it is to their interest to practise supplemental irrigation. A pumping plant has been installed on a fruit farm near the city, and experiments are being conducted. Last summer a peach orchard was irrigated with such remarkable results that already a great deal of interest has been aroused, and a number of farmers along the shore of Lake Ontario are installing pumping plants to supply water for irrigating their farm this summer. At Irondequoit, a market-garden town adjacent to Rochester, the Company is now supplying current at regular rates to more than 40 motors for farm use, most of which are for pumping water. The demand is increasing rapidly, and promises to reach large proportions this summer.

TELEPHONE INDUSTRY OF THE WORLD.*

The following figures have been obtained from various reports issued by telephone companies in all countries, and are believed to be the most complete *résumé* that has ever been published.



a = Africa, b = Australasia, c = Asia, d = America.

DIAGRAM SHOWING THE PERCENTAGE DISTRIBUTION OF TELEPHONES THROUGHOUT THE WORLD.

There were in use in the world on January 1, 1910, 10,269,000 telephone stations and 24,075,000 miles of wire, two-thirds of the telephones and wire mileage being in the United States. This is clearly shown by the diagram herewith. There is a race between Los Angeles, in the United States, and Stockholm, Sweden, for the honour of first place in the number of subscribers per inhabitant, Los Angeles leading with 61,000 stations and 240,000 inhabitants, and Stockholm following with 58,000 stations and 340,000 inhabitants.

The telephone investment of the world amounted on January 1, 1910, to £300,000,000, or nearly £30 per station, 65·5 per cent. of this total being on account of U.S.A. stations and 30·8 per cent. for Europe. The telephone conversations of the world for the year 1909 numbered 19,178,500,000, of which the United States used nearly 2½ times those of all other countries in the world.

The following table is of interest as showing the estimated number of stations per 100 population in the various countries at January 1, 1910:—

United States	7·6	Belgium	0·6
Canada	3·7	Argentine	0·5
Denmark	3·3	France	0·5
Sweden	3·1	Uruguay	0·5
New Zealand	2·6	Austria	0·3
Norway	2·3	Transvaal	0·3
Switzerland	2·0	Cuba	0·3
New South Wales	1·6	Hungary	0·2
German Empire	1·5	Italy	0·2
Great Britain	1·3	Cape of Good Hope	0·2
Luxembourg	1·2	Natal	0·2
Hawaii	1·2	Japan and Formosa	0·1
Victoria	1·0	Mexico	0·1
Finland	0·9	Porto Rico	0·1
Netherlands	0·9	Russia	0·1
Paraguay	0·9	Roumania	0·1
Venezuela	0·9	Spain	0·1

At the same date the number of telephone stations and miles of wire was distributed among the continents as follows:—

	Stations.	Miles of wire.
North America	7,342,700	16,167,300
South America	72,100	150,100
Europe	2,627,200	7,269,400
Asia	105,100	242,300
Africa	26,000	67,300
Australasia	79,500	149,200
Oceania	3,800	12,400
West Indies	12,600	17,000
Total	10,269,000	24,075,000

The countries with the largest number of telephone stations were the following:—

	Stations.		Stations.
United States	7,083,900	Norway	54,500
German Empire	910,900	Netherlands	52,600
Great Britain	615,900	Hungary	50,000
Canada	239,200	Belgium	42,600
France	211,600	Argentine	33,400
Sweden	171,400	New Zealand	26,800
Russia and Finland	155,715	New South Wales	25,000
Austria	99,500	Spain	22,000
Denmark	86,000	Victoria	12,500
Switzerland	73,300	Mexico	13,000
Japan	71,400	Brazil	11,900
Italy	56,400	Roumania	10,700

A comparison between the United States and Europe shows that Europe, with five times the population of the United States, has an estimated station development per 100 inhabitants of 0·6 against 7·6 in the United States; in other words, the telephonic development of Europe is one-twelfth that of the United States.

The difference in development between European countries and the United States is furthermore shown by the development of the German Empire, which leads all European countries with 910,900 stations, as compared with the development of New York State with 745,900. The latter exceeds by over 130,000 stations the development of Great Britain, which has the second largest number of stations.

The following table gives in detail the development of eight of the leading cities of Europe from 1894 to 1909. It should be noted, however, that while in most of the European countries the number of stations quoted corresponds to the area covered by the municipal

Telephones per 100 Inhabitants.

Jan. 1.	Stockholm.	Copenhagen.	Christiania.	Berlin.	Hamburg.	London.	Paris.	Vienna.
1894	3·5	1·0	2·6	1·2	1·2	0·1	0·6	0·5
1899	8·0	2·3	4·7	2·3	2·0	0·3	1·0	0·7
1904	13·0	4·4	5·4	3·3	3·5	1·2	1·7	1·0
1909	17·2	6·9	6·5	4·8	4·7	2·5	2·3	1·8

* Abstract of an article in the "Electrical Review and Western Electrician."

Digitized by Google

boundary of a given city, this is not true of the English cities included in the above comparison. There the stations quoted correspond in each case to a telephonic area, and the population figures are but approximate.

The gross revenue in Europe from telephone service for 1907 (latest figures obtainable) was about £15,000,000, and for the United States for that year £37,000,000. Most of the European countries, in which the telephone is a monopoly of the State and conducted as a branch of the postal and telegraph service, estimate that the telephone service *per se* produces a net revenue.

Comparing the telephone traffic of Europe and the United States with the first-class mail and the telegraph traffic for the year 1907 shows that in the United States, with a population about one-fifth that of Europe—

First-class mail traffic is 2·4 times that of Europe per 1,000 inhabitants.

Telegraph traffic is 1·2 times that of Europe per 1,000 inhabitants.

Telephone traffic is 12·8 times that of Europe per 1,000 inhabitants.

THE ELECTRIC VEHICLE OPPORTUNITY.*

BY H. EAMES.

The author points out the wonderful possibilities of the electric vehicle for central stations, showing that in the city of New York if only one-half of the horse-drawn vehicles were substituted by electric vehicles, the income from the current at 2d. per kilowatt-hour would amount to over £10,000,000 per year.

The electric vehicle business has inherited a great many things from other businesses that are more or less analogous to it, but which are, by no means, exactly similar. The consequence is, if you act on impressions, you may get momentary advantage at the expense of ultimate success. During the 15 years that the manufacturers have been engaged in pushing that business they have had occasion to know what the real problem is. The assertion that business waggons have not improved in an engineering way in the last 10 or 15 years would not be true. They have improved, but the point that impresses one upon an investigation of the history of their improvement is that as much as 10 years ago the power electric waggon had already reached the degree of economy that made it more economical than horses for all service—for all service within certain limits. It is because the people have failed to take the next step that it has been kept back all these years, and is still being kept back.

The author next dwelt at some length on the extreme measures necessary to educate the public in the use of electric vehicles, and said that the bulk of this work would necessarily fall upon the central station. When these organisations have informed themselves on these questions, have recognised their great importance, and have made it their business to see that the first local power waggon shall be carefully bought and intelligently used, they will have made a long stride towards getting the benefit of this new market for current. These things are intangible, but, after all, the whole thing is mental, and these are mental problems, the solution of which will produce an immediate and tremendous demand for current for power waggons. To make this education effective, to be in a strong position to regulate local introduction, to see that a proper application of vehicles is made, to see that, for instance, electric waggons are not used where gasolene waggons would give better satisfaction, and vice versa, it is essential that central stations maintain a judicial position. While, no doubt, every manufacturer would be glad to have the direct aid of central stations in the local distribution of his vehicles, this could not fail to retard local educational work. It would undoubtedly stimulate large competitive interests to an active propaganda in favour of independent power stations, and these, in many cases, would be amply justified by the amount of power-waggon current required. Under existing conditions, the most healthy, strongest and most promising line of action for central stations will be to establish themselves as sources of information and to use the moral influence this will create to insure for their localities, always under their own tacit control and direction, the full benefit of the efforts of all competitive electric waggon manufacturers. Central stations must also see that owners of electric vehicles don't want to put in independent plants.

DISCUSSION.

Mr. P. D. WAGNER (General Vehicle Co.) said that one reason why the electric vehicle had not received the support of the central station had been because in the past, after the electric vehicle was sold, the purchaser was left to work out his own salvation, the result of which had been a dissatisfied customer. He said that there was an honest attempt on the part of all vehicle manufacturers to-day not to sell an electric vehicle unless they honestly believed that it was fitted to do the work.

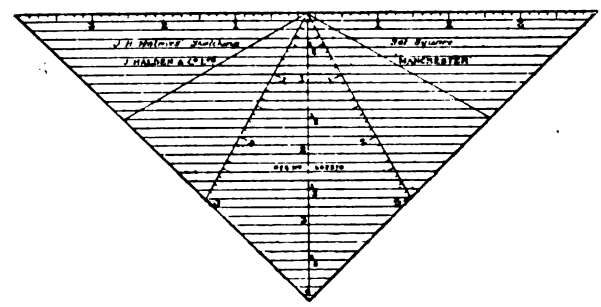
Mr. W. H. BLOOD, Jr., said that the electric vehicle business and the charging of storage batteries for them was to-day the best undeveloped prospective load in sight for the central station. Besides being a load of large proportion, it was an off-peak load. He explained the functions of the Electrical Vehicle and Central Station Association which has recently been formed in Boston and spoke of its future prospects. He also refered to a co-operative movement on foot between vehicle manufacturers to advertise the electric vehicle extensively.

Mr. G. H. JONES (Chicago) said that the Commonwealth Edison Co. believed very earnestly in the great future of the electric vehicle business. He said that in order to bring this matter before the people, the Company was carrying on two forms of educational campaign: One, to bring the matter before the non-users, and the other to educate those who had machines to operate them correctly.

* Abstract of a Paper read before the National Electric Light Association.

A NEW SET SQUARE.

Messrs. J. Halden & Co., of Manchester, have sent us a sample of a new set square they have just placed upon the market. It is made of celluloid, and comprises in one instrument straight-edge and parallel ruler, scale, protractor and set square. It should be specially useful for drawing centre lines and lines at right angles to them, series of parallel lines at definite distances apart, lines at various angles, and for making drawings in isometric projection. The "apparatus" is shown in the accompanying illustration.



NEW SET SQUARE OF MESSRS. HALDEN & CO.

The usefulness of this design of set square is dependent upon the transparency of the celluloid of which it is made. By reason of the transparency it is possible to lay the set square down upon any line already drawn so that some line ruled upon the set square exactly coincides with it, and then, by using some edge of the set square as a ruler, other lines may be drawn at definite angles to, or at definite distances from, and parallel with, the line first drawn.

ACCUMULATOR CARS FOR TRAMWAYS.*

In the latter part of March of this year the Third Avenue Railroad of New York placed in service a storage battery equipment on a converted horse car. This pioneer car has been so successful that an order has now been placed for 30 similar equipments. Twenty-five new car bodies are to be built and five old horse-car bodies are to be rebuilt for this purpose in the shops of the Company. The motor equipments and control will be furnished by the General Electric Co., and the storage batteries will be supplied by the Gould Storage Battery Co. A feature of the contract with the latter C mpany is an agreement to maintain the accumulators for five years at a fixed price per car-mile. The battery company have agreed to do all necessary cleaning, furnish all renewals of chemicals and water, make repairs and generally maintain the efficiency of the cells in good operating condition. This contract is said to be the first of the kind ever made.

The cars will be 26 ft. 5 in. long over all and 6 ft. 5½ in. wide. The platforms will be about 4½ ft. long and designed for prepayment operation like the other cars of the Company. The car body proper is 18 ft. long and will have longitudinal seats for 24 to 26 passengers. Under the seats on each side, a space 17 ft. long by 12 in. wide by 15 in. deep will be provided for the batteries. Room has also been left in front of the battery casings under the seats for piping in case it is decided to use hot-water heaters in these cars. These pipes would be covered by perforated iron sheets. In general, the car bodies will be constructed of wood throughout, and will be mounted on single trucks.

The storage battery equipment will consist of 58 cells of the Gould 29 T.-H. type, having a capacity of 420 ampere-hours when discharged at a 70-ampere-rate and at a temperature of not less than 80° F.

* Abstract of an article in the "Electric Railway Journal."

Digitized by Google

It is defined in the contract that "battery operating condition" means maintaining the efficiency of the batteries to at least 75 per cent. of their rated capacity. The motor equipment per car consists of two G.E. automobile type motors rated at 30 ampere capacity at 125 volts. The motors and the trucks will be furnished with ball bearings. The type of silent chain drive has not yet been selected. With this electrical equipment it will be possible to maintain a regular schedule speed of 7 miles per hour, allowing eight stops per mile. The total weight of the car body, truck and equipment will be approximately 6 tons. The cars will be operated on practically level streets now served by horse-cars.

LEGAL INTELLIGENCE.

Torquay Tramways Arbitration.

Mr. Archibald Read sat in London this week to arbitrate between Torquay Corporation and the Torquay Tramways Co. as to whether the consent of the Corporation to the installation of the overhead system of traction on Nos. 5 and 5A of the tramways is unreasonably withheld. The Board of Trade had previously approved plans submitted by the company for the overhead system, so far as the safety of the public is concerned, and without prejudice to any legal questions as to the proposed change.

The ARBITRATOR said the Torquay Tramways Act, 1904, provided that the consent of the Corporation to the use of any system other than the Dolter surface contact system shall not be unreasonably withheld, and the tramways above referred to, and which were transferred to the Torquay Tramways Co. under the Torquay and Paignton Tramways Act, 1909, came into dispute, as the company wished to adopt the overhead system thereon and the Corporation did not assent.

Mr. H. LLOYD, K.C. (with him Mr. Courthope-Munroe), for the Corporation, protested that the arbitration was asked for under sec. 61 of the 1904 Act, whereas it should be under sec. 58, sub-sec. 15, which was the only section for settling disputes of the nature now under discussion. An agreement dated Jan. 2, 1906, between the Dolter Co. and the Corporation also provided that tramways 5 and 5A should not be constructed on the overhead trolley system without the consent of the Corporation, and he submitted that that was not subject to any arbitration. He, therefore, proceeded under protest. The Corporation claimed the absolute veto, and he would ask the Arbitrator to either state a case at once or to give his decision in the form of a special case.

Mr. VESEY KNOX, K.C., who (with Mr. Phillips) appeared for the company, said they had had no notice that any objection to the arbitration would be taken by the Corporation. Unless the company had some other system substituted before the end of October next they would have to stop running their tramways. The Corporation had had two months' notice of these proceedings. The Corporation ought to have had this question of jurisdiction settled long ago. It was clear that an arbitrator could be appointed under sec. 61, which said "Where the consent or approval of any local authority is by this Act required before the exercise of any powers by the company such consent shall not be unreasonably withheld." That was in general terms, and there could be no justification for assuming that Torquay Corporation was excepted. The agreement mentioned by Mr. Lloyd could not add any force to the Act of Parliament. He would be content to go on with the proceedings and leave the question of the section which applied to be settled hereafter. Mr. J. Swinburne, an expert witness, had to go to America, and it would be convenient that his evidence should be taken now. The bulk of the expense had already been incurred, and it would be more convenient if the proceedings went on, subject to the question raised by Mr. Lloyd. The company attached great value to the evidence of Mr. Swinburne, and they could not get it unless they took it now.

The ARBITRATOR said he would go on with the arbitration and state his decision in the form of a special case.

Mr. VESEY KNOX said Mr. Waller drew up a tramway scheme originally on the overhead system. In 1902 the Corporation took a postcard poll, which resulted in a majority in favour of the construction of tramways, but against the Corporation carrying out the work themselves. There was no question then as to the system of traction. The overhead system was cheap, reliable and safe, but the conduit system was much more expensive.

Mr. LLOYD: I am not going to suggest the conduit system.

Mr. KNOX said the first cost of the surface contact system did not, perhaps, exceed that of the overhead by more than £1,000 per mile, but it was not reliable, and cost much more for upkeep. The Board of Trade had never given more than a provisional approval to the use of the Dolter system in Torquay. There were provisions as to poles, brackets, &c., in the 1904 Act which could be applied in case of the surface contact system proving to be a failure. It was to the interest of the Corporation to keep the company's system at the lowest value until they bought it up in 1914, and, therefore, he could not help thinking that was in their minds when they withheld their consent to the change of system.

Mr. LLOYD said sec. 30 of the 1909 Act gave the company a longer period.

Mr. VESEY KNOX: Only if the Corporation did not exercise their right to purchase in 1914.

Mr. LLOYD thought it might shorten the proceedings if he interrupted to state his position. Having regard to the particular route, the feeling in Torquay, the possibility of the amendment of the Dolter system, and the availability of other surface contact systems, the Corporation had not been unreasonable. He said the Dolter system, plus the Mitchell stud, was perfectly satisfactory, and the Lorain and G.B. systems would also be satisfactory.

Mr. VESEY KNOX said the Board of Trade would not sanction the G.B. system. He went on to say the Board of Trade were forcing them to remove the Dolter system, and he submitted that the company were entitled to put down the overhead system, which had been approved by the Board of Trade for all the lines except 5 and 5A. Mr. Mitchell had invented five forms of stud which the company had tried without success. At Mexborough the overhead system, which was substituted for the Dolter system, used 1·7 units per car-mile, compared with the previous figure of 2·3, cost of maintenance went down from 3d. to 1d., and the average takings rose from 7½d. to 10d. At Hastings the Dolter system was still worked, but under specially favourable conditions and at double the cost of other parts of the line for maintenance. The company had prepared a financial scheme for the proposed overhead system which would cost about £60,000 in all, but it had been proved that no financier would touch a surface contact system. The great point of Mr. Mitchell's latest invention seemed to be that one pot only would be used to enclose the mechanism operating the stud to keep out water, instead of two as formerly, which seemed to him to be bad on the face of it. Another difficulty was that when the oil used in the pots to keep out water became carbonised it became alive, causing the stud to be continuously alive. The new invention would only lengthen the period in which the oil would become carbonised. A third trouble was the formation of gas (the cause of which had not been discovered) and consequent explosions. Since a specification for this invention was filed in 1908 Mr. Mitchell seemed to have abandoned the single pot to some extent, and adopted a compromise between a single and double pot, which he (counsel) thought would permit still more readily the infiltration of water.

Mr. W. B. COWNIE, a director of the Torquay Tramways Co. and secretary and general manager of the National Electric Construction Co., said the surface contact system was estimated by engineers to cost £1,000 per mile more than the overhead (or £2,000 per mile in all), but it had cost them considerably more. The conduit system had cost £18,000 per mile in London. Mr. Mitchell was formerly the National Co.'s chief engineer, and afterwards left them and went to the Dolter Co. At Mexborough about £10,000 was spent on trying to improve the Dolter system after the construction was finished.

Mr. PHILLIPS read a letter (dated Sept. 10, 1910) from the Board of Trade to the company's solicitors, stating that the Board would not approve the use of the G.B. system at Torquay, and they were not prepared to say that they would approve of the Lorain system.

Mr. COWNIE (continuing) said it cost about £8,000 to put up the overhead system in Torbay-rd. If they were compelled to have surface contact or conduit on the Torbay-road he did not think they would go on with the Paignton extension. The Corporation seemed to think that if the company used the overhead system they would not be such good customers for current as at present. That was a fallacy, as they would increase their service. Their current at Taunton cost them 1·6d. per unit, and the units used per car-mile were 2·3.

Mr. LLOYD said there was nothing in that agreement about the Corporation's consent being unreasonably withheld. In another agreement in 1906, which gave some concessions to the company by allowing them to proceed with certain lines earlier than they could have done under the act, there was again no reference to unreasonable withholding of consent to the overhead system on tramways 5 and 5A.

Mr. COWNIE said he had come to the conclusion that the Dolter system was pretty well doomed. If, however, the Corporation were satisfied with the Dolter system he was. But for the action of the Board of Trade they would have had to go on, and would have gone on as long as they could. The Lorain system seemed to work all right when he was on it. The G.B. system at Lincoln did not work all right when he was on it. One of his objections to the Lorain system was that he could not get any one to put it down, and after his experience he had no faith in any surface contact system. The overhead was the only feasible system for them. A constructing company would give a guarantee at once for the overhead system, but no contractor would guarantee a surface contact system.

Mr. VESEY KNOX contended that, as a matter of law, the provision in the agreement of 1906 that certain tramways should not be constructed on the overhead system without consent was ultra vires. It had been held that a company had not power to bar themselves of a statutory right, and moreover the Torquay Co. did not know of the agreement when they took over the Dolter Co.'s undertaking, and these facts would rule out the necessity of the arbitrator's considering the agreement from the point of view of reasonableness. It seemed that they could have as much overhead as they liked if they gave every councillor a direct route to the new town hall. The best terms they could get from the Lorain Co. were £2,681 per mile of single track. The Lorain Co. also declined to give a guarantee, and it was absolutely impossible to raise the money for putting down the Lorain system without such a guarantee.

Mr. JAMES SWINBURNE said he was familiar with the Dolter system. Overhead tramways were constructed in beautiful cities on the Continent while the objection to overhead wires was still being persisted in by manufacturing towns in England. The conduit system was quite practicable from an engineering point of view; it was only a question of expense. There had been an enormous number of patents for surface contact systems. It could not be said that surface contact had been proved satisfactory, although a particular man might be found who was satisfied with it. He thought the Dolter system had proved a decided failure. It was particularly difficult to design a satisfactory surface

Digitized by Google

contact system for Torquay, because the roads were sometimes flooded and at other times they were watered with sea water, and he also understood the road was not very firmly constructed. It was very difficult to find oil of sufficient specific gravity to keep out water and also with so slight a viscosity that the lever would work in it. Water probably got into the pots because any air underground was probably saturated with moisture, so that any reduction of temperature would cause a little moisture to condense, and if the water got down in the inner pot under the oil it had not a chance of evaporating, and so it was a kind of water trap. The water would make contact with the two parts in the pot and cause a short-circuit. Witness was shown a drawing of Mr. Mitchell's latest modification of the pots to suit the Torquay track, and said it might have some advantages and some disadvantages. It did not, in his opinion, show sufficient improvement to make the difference between success and failure. It was quite unreasonable to come to the Torquay Co. and say, "Here is a system which exists on paper. You must put this down." The improvement, if any, in the pots would probably not be sufficient to induce the Board of Trade to sanction its use at Torquay. He could not think of any oil which would be sufficiently thin to allow the lever to work and yet be of sufficient gravity to keep out sea water. In his opinion it was unreasonable to object to the overhead system in Torbay-road. It would be a great drawback to have the Lorain and also the overhead systems. He did not remember that Mr. Mordey's report mentioned any oil suitable for the pots. He was not satisfied with Mr. Mordey's recommendation of Mr. Mitchell's system. The carbonisation must take place in the one pot as it did in the two pots. He had not investigated the Lorain system. It had received careful attention by electrical people, but it had not been adopted except (he believed) at Wolverhampton. He thought if the Lorain system had been a practical success it would have forced its way to the front.

Mr. J. L. BRIMAVESIN, assistant engineer to the National Electric Construction Co., said they had tried several oils for the pots. They got one which was heavier than water and allowed the lever to work, and they got a guarantee that it would not affect the bitumen, but they found that it did after a time. He confirmed Mr. Cownie's statements as to the current used per car-mile and the traffic receipts at Mexborough. The maintenance cost per car-mile was 2·5d. for the Dolter, compared with 0·106d. for the overhead.

Mr. J. S. BRAITHWAITE said he had no connection with the Torquay system. He did not think it would be possible to raise money for a surface contact system.

Mr. BRIMAVESIN, cross-examined, said the composition of the oil used in the pots had been altered from time to time. Some of their accidents were caused by the oil escaping from the outer pot either owing to the breakage of the pot or its breaking through the seal at the bottom. The faults were apparently increasing in the present year.

Mr. H. HOLLIDAY, engineer and manager of the Torquay Tramways since March, 1907, confirmed statements by previous witnesses as to various modifications of the studs introduced by Mr. Mitchell, and subsequently abandoned by the Torquay Co., and also as to the company's experience with the oils used. They had tried widening the brush used to detect live studs, so that it would operate at curves, but when they widened it to more than 50 in. it touched the stud (which might be alive) and also the rail, and the result was that the current did not ring the alarm bell on the car but went direct to the rail. Compensation paid for accidents other than those caused by live studs was £45 in 1908, £31 in 1909 and £3. 13s. up to August this year. For the week ended Sept. 1 the units per car-mile registered by meters on the cars were 1·94, but the units per car-mile as measured at the station were 2·20. This meant a loss of £679 a year.

Mr. W. H. PATCHELL said alterations had been made in the Dolter system at Torquay which had been beneficial, but there were radical defects which never could be improved. In the commercial and every other sense he thought the system hopeless. He saw no way of dealing with the trouble of the water in the pots. He did not think the live studs could be eliminated.

Mr. LLOYD, in his address on behalf of Torquay Corporation, said he had to register a protest against the arbitration taking place, as there was an important question of law which his clients wished to raise. He contended that the Corporation's right, under the Act of 1904, to consent or not to consent to tramways in Torbay-road was absolute, and not subject to the control of anybody. It was not correct to say the ratepayers decided to have tramways on the assumption that they should be on the overhead system. In the agreement dated Jan. 14, 1904, the Corporation waived their claim for a financial guarantee for the Dolter system in consideration for their being given the option of having or not having a tramway on the Torbay-road, and secondly if they decided to have such a tramway that it should be on the Dolter or other surface contact system, but now that the Board of Trade said the system was inefficient and unsatisfactory the company were going to say not that they would go away or wait and see if they were required by the Corporation to put in another system, but that they would force upon Torquay that to which the Corporation had said they would never submit. Supposing that, as a matter of law, were decided in the company's favour, the question was to be considered whether the Corporation were acting unreasonably in saying they would not have that to which from the outset they said they would never consent. The Corporation preferred the Lorain system to the overhead, and it was not a question whether the company was making a profit or whether the surface contact system cost more to work than the overhead.

Mr. C. E. C. SHAWFIELD, borough electrical and tramway engineer, Wolverhampton, stated that the Lorain system at Wolverhampton, of which there were 21¾ miles of track in operation, had worked entirely satisfactorily. The first portion was opened in May, 1902. The average working costs for the last three years were 6·4d., and total costs including capital charges 9·37d. Live studs (giving a reading of 100 volts or over) were only equivalent to half a stud per mile of track per annum. During the last seven years the total live studs, including those below 100 volts, averaged two studs per mile of track per annum. The live studs at Wolverhampton were often due to the picking up of scrap iron by the cars, which caused a short-circuit between the stud and the rail. So far as his acquaintance with Torquay went he saw no reason why the Lorain system should not be suitable for Torbay-road, although the flooding of the road by sea water would be detrimental to the working of any electric tramway system. His present knowledge would not justify him in recommending the laying down of the Dolter system. Before he adopted a system in which a switch had to work in oil, he would require a very wide evidence that such a thing was possible. He regarded the Lorain as the safest and most reliable system. At Wolverhampton they had never had a car stopped owing to defects of the surface contact system, but they had had a stoppage from failure of the feeder cable, which would have occurred equally on the overhead system.

Mr. W. A. LUNTLEY, general manager of the Wolverhampton Corporation tramways, confirmed Mr. Shawfield's evidence as to the working of the Lorain system, and the arbitration was adjourned until to-day (Friday).

Bogus Claims for Compensation.

At the New Bailey (London) on 9th inst., three men, named Weller, Smith and Hodder, were sentenced to six months, four months and one month respectively (with hard labour in each case), for obtaining money by false pretences and for conspiring to attempt to obtain money in connection with compensation claims for bogus accidents. The prosecution was at the instance of the British Electrical Federation, and was in connection with the Metropolitan Electric Tramways (Ltd.) operating in the north and north-west London districts.

Mr. J. RATCLIFFE COUSINS (instructed by Mr. Hugh C. Godfray) prosecuted, and gave an outline of the operations of the prisoners, who form part of a gang which has been perpetrating these fraudulent claims for the past five or six years. The leader of the gang was Weller, who had a permanent injury to his right wrist, and with this asset has been able not only to get a good living for himself, but has assisted others of the gang to obtain considerable sums of money from insurance companies, brewery companies, tradesmen and others, in addition to the tramway companies. So far as the tramway companies claims are concerned Weller's method was to board one of their cars and secure a seat on the top deck. When the car got to its destination he would allow the other passengers to alight, when by means of some weapon which he carried in his pocket he would break away a piece of the wood slatting or beading which is nailed across the top deck, and would then pretend to fall, and proceeding downstairs would inform the conductor that he had met with an accident through falling over the defective slatting. His name and address would be taken, and in due time his claim would be received for compensation. Weller would, in the meantime, attend one of the London hospitals, where the practice is as follows: If a person wants medical attendance as an out-patient he simply sees the hall porter and states the nature of his injury, the porter fills in a form recording this injury, and with this the patient is directed to attend the house surgeon at the out-patient department between certain hours for treatment. Hitherto these documents have been regarded as certificates showing that the claimant was actually suffering from the injury stated. It is clear, however, that a fraudulently disposed person can make use of same in promoting the claim against his victims. From the evidence given by the police Weller has successfully carried on this practice for a number of years by simply appearing at different hospitals under different names and at intervals securing a fresh document when required. The other members of the gang came into the conspiracy from time to time, as it was obviously impossible for Weller to appear more than once at the offices of the various firms he defrauded without fear of detection. He conspired, therefore, with the other prisoners that he would when necessary give their names and addresses as his own, and when the company or firm on whom he claimed sent their representative to interview the claimants Weller had meantime bandaged their right arms in correct hospital fashion and provided the conspirators with this useful hospital document in order that the chain of evidence would be complete. As the sum claimed was usually small, varying from £2 to £15, it was an easy matter for the frauds to be successful. In the case of the Metropolitan Tramways Co. they had in one accident a report from the conductor of the car in which Weller travelled and also a detailed report from an inspector who happened to be travelling on the car at the time of the alleged accident, and when the company's representative saw the prisoner Hodder he was bandaged up in this fashion and produced the hospital document in his own name, stating the injury as a fractured right wrist. The whole case appeared to be genuine, and a prompt settlement was made in order to avoid legal proceedings which were threatened unless the company agreed to pay quickly.

Although the British Electrical Federation were only victimised in a few cases they considered it their duty in the interests of the public to institute proceedings, as although several of the large insurance companies in London had been aware that a gang had been at work for some years past and they had been victimised to a much greater extent, they had been unable so far to detect the offenders. The fraud was discovered in the following manner: Weller, writing in the name of Smith from an addressat Walthamstow, informed the Metropolitan Tramways Co. that he had met with an accident on June 20 last and made a claim for compensation. A report had in the meantime been received from the conductor of the tramcar, and these documents were in due time forwarded to the

Digitized by Google

department which deals with claims against the companies in the Federation. The claims officer made inquiries, and discovered that a similar claim had been settled a few days previously by a local tradesman, the claimant being of the same name, but giving an address at Wood Green. This address happened to be that of the prisoner Hodder, who had been paid compensation some six months previously for an accident identical in its nature to the one now claimed for. In response to a letter Weller called at the Federation offices, and was interrogated about the accident. He produced the hospital document describing the nature of his injury, and it was noticed that the date on same had been altered. He was induced to make a statement in writing, in which he asserted that he had never met with an accident before and had never been paid compensation by any other firm. He was told to come back again to receive the money which he claimed as compensation, and in the meantime inquiries were made which proved that the certificate had been issued on May 30 last to Weller in the name of Smith, but the address given was Wood Green, and on the strength of this certificate he had already been paid compensation by a local outfitter for injuries said to have been sustained through falling over his sunblinds, which were projecting at the doorway of his shop. It was also ascertained that his statement was false in other particulars, and when he appeared at the Federation offices next day two Scotland Yard detectives, who were present in an adjoining room, overheard Weller repeat the false statements made on the previous occasion, and he was arrested. On being searched documents were found in his possession which led to the arrest of Hodder, who made a confession showing how the conspiracy had been worked. Smith was meanwhile actively engaged in endeavouring to obtain money from tradesmen in other accidents for which Weller had provided him with the useful hospital document, and he was in due time arrested.

A warrant was obtained for the arrest of a fourth member of the gang, but he had in the meantime decamped.

The publicity given to the cases in which these men have been concerned will have a useful effect, and in passing sentence on the prisoners Judge Rentoul stated that if the press would give more prominence to such frauds, which have become very frequent of recent years, it would act as a deterrent on others.

Mining Regulations.

Application has now been made to the Sheriff of Linlithgow on behalf of the Home Office to state a case with the view of appealing to the High Court of Justiciary in the recent prosecution against John Leckie, mine manager at No. 3 Pit, Blackridge, belonging to the United Collieries (Ltd.). Respondent was charged with having failed to see that a competent person was on duty at the pit when the electrical apparatus and machinery were in use at the pit, as required by Rule 11 of the special rules for the installation and use of electricity in mining, but Sheriff-substitute Macleod found the charge not proven.

The case was reported in THE ELECTRICIAN for Sept. 2.

Valuation Appeal.

On Tuesday the Lochleven Water Power and Electric Company (Limited) appealed to the local Valuation Appeal Court against their assessment (£35,000) for last year. The Court fixed the valuation at £30,500, being 5 per cent. of total capital expenditure, but on account of the works not being fully completed at August 12, the Court restricted the valuation to £10,170 for last year. In respect to this year's valuation the assessors explained that they had fixed it on the principle of taking 5 per cent. on the total capital expended, admitted by appellants as heritage, and applying the principle of last year, they estimated the valuation this year at £35,000, which they were willing to restrict to £32,000 on an adjustment of total capital expenditure with appellants up to date. Appellants claimed to be rated on profits of one year, and gave evidence in support.

The Court, in giving their decision, stated that last year in fixing the value at £10,170 the committee proceeded upon the only method then open to them, namely, a percentage on capital outlay. It had been represented to them that the condition of working during the past 12 months had resulted in a profit of £20,450, against which certain figures had been set that more than absorbed the profit. The committee were of opinion that the figures relating to the last six months, compared with the first six months of the year, along with other evidence in the case, showed the prospects for the year 1910-11 were better than for the year that ended on May 15 last, and accordingly they felt justified in coming to the conclusion that the current year would be more successful, and, keeping that in view, they fixed £7,500 as a fair assessable value, which sum compared with a rate of 1¾ per cent. upon the capital expenditure on the works.

The assessors asked for a stated case to be laid before the Court of Session.

Village Lighting.—The village of Askrigg, which has for many years been lighted by oil lamps, is now brilliantly illuminated by electric lamps.

Mr. W. F. Burton, of Millgill, had a water-power plant put down for his own use, and having a reserve of power, offered Askrigg Parish Council to provide the public with electric light. After consideration the offer was accepted, and the main street and several places are now illuminated with lamps of 50 c.p. The Wesleyan Chapel, the school-room, the Hotel, and many private houses are also lighted electrically.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

Applications are invited for the position of resident engineer for one of the electricity works under the control of the County Borough of Stoke-on-Trent. Applicants must have a thorough mechanical training and experience in a three-wire d.c. station. Salary £180. Forms of application from the chief electrical engineer, Mr. C. H. Yeaman. Applications to the town clerk, Mr. E. B. Sharpley, by 26th inst. See also an advertisement.

There is a vacancy for an improver (without salary) at the Watford electricity works; also for a premium pupil. Applications to the Chief Electrical Engineer. See advertisement.

Wireless telegraph operators are required for the Canadian Navy; must be experienced men of good character. Particulars from the Captain, H.M.C.S. "Niobe," Devonport. See an advertisement.

An assistant engineer is required by an English company operating in South America; must have had experience in station running and three-phase h.-t. working. Commencing salary £250 per annum. See an advertisement.

A telegraph and electrical instrument inspector is required for the Baro Kano Railway (Northern Nigeria) for two tours of 12 months' residential service, with possible extension. Salary £250 a year, rising to £300 by annual increments of £10. Applications to the Crown Agents for the Colonies, Whitehall-gardens, London, by 17th inst.

The Yorkshire Electric Power Co. has a vacancy for an assistant engineer in the construction department. Salary £156 per annum. Applications to the company at Thornhill, Dewsbury.

An electrical engineer is required to take charge of the Cambuslang electricity and refuse destructor works of Lanark County Council. Commencing salary £160. Applications by Sept. 26.

Three professors of physics are required for the Government colleges at Rangoon and Dacca. Particulars from the Secretary, Board of Education, Whitehall, London, S.W. Applications should be marked "C.A."

Mr. W. Gallow Duncan, M.I.M.E., late head of the Indian Government Engineering College (Dacca), has been appointed lecturer in heat engines and applied electricity at the Modern School, Bedford.

"The Electrician" Electrical Trades Directory and Handbook.—For the examinations of the Insurance Institute of Great Britain and Ireland, which will be held in March, 1911, "The Electrician" Electrical Trades Directory and Handbook is one of the text books recommended for the examination in the fire branch.

EDUCATIONAL NOTICES.

University of London, University College.—The 1910-11 session begins on Monday, Oct. 3. Complete courses of study, extending over three years, are arranged in mechanical, electrical, civil and municipal engineering. Students desirous of entering the faculty of engineering with the view of taking a full degree or diploma course must have passed the matriculation examination or some other examination accepted in its stead. Students who have already attained a sufficient standard may enter for a course occupying less than three years, and may obtain a general certificate of engineering after not less than two consecutive sessions. Graduates in science or engineering, or students who have done the work equivalent to a degree, may be admitted to special courses of study or to prosecute original research. Intending students should communicate with the Provost as soon as possible, and in any case not later than Sept. 20. Full particulars from the secretary, Mr. Walter W. Seton, M.A., Gower-street, London, W.C.

University of London, Goldsmiths' College.—The new session commences on Monday, Sept. 26, and the enrolment of students commences on 19th inst. Complete courses of instruction are provided in mechanical, electrical and constructional engineering, telephony, fitting and machine pattern making and smithing, land surveying, &c. Students are prepared for the London University degree of B.Sc. in engineering, for the examinations of the Institution of Civil Engineers, Board of Education and City and Guilds of London Institute and for the National and Whitworth scholarships. There are reduced fees to course students if paid by Sept. 23. Particulars of fees, &c., from the Warden, Goldsmiths' College, New Cross, S.E.

University of Edinburgh.—The next session opens on Oct. 4, and the preliminary or entrance examination is held in September. In

Digitized by Google

the engineering department of the University complete courses of instruction are provided in civil, mechanical and electrical engineering, qualifying for the degree of B.Sc. in Engineering, and extending over a period of three years. Particulars of entrance examination scholarships, fees, &c., can be obtained from the Matriculation Office of the University.

Armstrong College, Newcastle-on-Tyne.—The next session commences on Sept. 26. The matriculation examination takes place on Sept. 20-23. There are full courses of instruction in mechanical, marine, civil and electrical engineering, naval architecture, mining, metallurgy, agriculture, pure science, arts and letters. Particulars from the secretary, Mr. F. H. Pruen, M.A., Armstrong College, Newcastle-on-Tyne.

Sir John Cass Technical Institute.—At this institute there are evening classes in chemistry, metallurgy, physics and mathematics, and the courses are designed to meet the requirements of those engaged in chemical, metallurgical and electrical industries, and in trades associated therewith. Facilities are given for special and advanced practical work in well equipped laboratories both in the afternoon and evening. The instruction in general physics and mathematics will prepare for the final B.Sc. examination of London University, and there are special courses on general physics and electricity and magnetism for the honours B.Sc. on induction in gases and radioactivity and on the differential and integral calculus for science students. The new session begins on Monday, 26th inst. Particulars of the courses can be obtained at the offices of the Institute, Jewry-street, Aldgate, London, E.C., or by letter of the Principal.

King's College (University of London).—In the Faculty of Engineering complete courses of study, extending over three or four years, are arranged in civil, mechanical and electrical engineering for the engineering degrees of the University of London and for the diploma and certificate of the College. There will also be special courses of advanced lectures on "Internal Combustion Engines" and "The Theory and Practice of Construction." The entrance day for new students is Tuesday, Oct. 4.

University of Bristol.—At this university complete courses of instruction in electrical, mechanical and civil engineering are given, and also instruction in the evening classes. The 1910-11 session in the faculties of arts, science and medicine will commence on Oct. 3, and in the faculty of engineering on Sept. 13. Particulars and prospectuses from the registrar, Mr. James Rafter.

Merchant Venturers' Technical College. Bristol.—We have received a copy of the calendar for the 1910-11 session of this college, which now provides instruction in the faculty of engineering in the University of Bristol. The calendar gives full particulars of the courses of instruction, fees, scholarships, examinations, &c. There are day and evening classes, and well-equipped laboratories for practical work and research. Copies of the calendar can be obtained at 6d. each.

Battersea Polytechnic (London, S.W.).—The day courses at this Polytechnic prepare for the B.Sc. degree (in engineering) of the University of London, and for the Polytechnic diploma in mechanical, electrical, civil and constructional engineering. The day courses commence on 22nd inst. and the evening courses in the same subjects on 26th inst. Prospectuses from the Secretary.

The calendar of the polytechnic for the coming session indicates an increase of work in all departments. In connection with the engineering and building department, new evening classes are being commenced in pattern making and architectural measurements. The chemistry department is extending its work by providing more advanced instruction in paper making and bacteriology, and new classes in soap manufacture. The mechanical and electrical and physics laboratories, built last year, are now being equipped, and these (with the extension of the art and women's departments) will provide more extended and complete work in these departments than was formerly possible. The new library, presented by Mr. Edwin Tate, at a cost of £8,000, to be opened by the Archbishop of Canterbury on Oct. 21, will be a valuable addition, and will render the Battersea Polytechnic one of the most complete educational institutions in this country.

Borough Polytechnic Institute.—The new session begins on 26th inst. There is a four years' course of instruction in electrical engineering, and in electric wiring there is a three years' course. There are day and evening classes. Further particulars and detailed syllabus are given in the prospectus, which can be obtained from the Principal, Mr. C. T. Millis.

Northampton Polytechnic Institute.—At this institute there are day and evening courses in engineering (mechanical and electrical), electrochemistry, technical optics, in artistic crafts and in horology. The engineering courses include in sub-sections automobile work, aeronautics and radio-telegraphy. In addition, there are evening courses in metallurgy and domestic economy. The classes of the day courses commence on Oct. 3 and those of the evening courses on Sept. 26. Enrolments for the latter commenced on the 12th inst. Full details of the syllabuses and the equipment are given in the "Announcements" for the 1910-11 session, which has just been issued.

The new building at Clerkenwell, London, the pending utilisation of which was notified a year ago, has proved a very valuable addition to the accommodation of the Polytechnic, and has allowed developments in several directions which have been previously hampered by lack of space. In the electrical engineering department the new generating station, which has been installed during the spring and summer of this year at a cost of about £6,000, will be available for the instruction of senior students. This station, which will be opened on Oct. 12 by the Chairman of London County Council, is thoroughly equipped in all details for the generation and distribution of continuous and alternate currents. The work of the department, hitherto in charge (under the personal direction of the principal) of Dr. C. V. Drysdale, will, during the coming session, be in charge of his successor (Mr. F. M. Denton), whose appointment as associate head of the department was announced last Easter. In the department there are also consolidations in the courses in telegraphy and telephony. The classes in submarine cable work are being continued, and more advanced classes are projected in radio-telegraphy, although this subject has been treated hitherto as an advanced subject in the work of the Polytechnic.

In the mechanical engineering department the success of the pioneer courses in aeronautics which were given last winter has been so marked that the subject is being developed for the coming winter and extended to the day courses. In the evening courses and classes, the subject of aeronautics will be placed in the charge of Mr. F. Handley Page, of the firm of Handley Page (Ltd.), aeronautical engineers.

In the technical chemistry department there are modifications in the day courses which are intended to bring the instruction in electroplating more into line with the actual requirements of the trade. These modifications have been made in consultation with some of the leading employers. The pioneer evening class in metal colouring which was held last session having proved a success, is being continued this session with some developments.

In technical optics arrangements have been made to extend the advanced work in sight testing and physiological optics and to develop the classes in other directions.

BRITISH NOTES.

Belfast.—For a long time complaints have been made of the inadequate lighting of some of the business thoroughfares in this city, and the Corporation recently decided to do something to improve matters, and resolved to light the High-street and Castle-place by flame arc lamps.

The lamps will be suspended from a main wire carried upon special span wires, along the centre of the street about 2 ft. higher than the tram trolley wires; these span wires being stretched from the tops of the tram poles. The wires and feeders have been erected by the electric supply department, and the lamps are ready to be placed in position.

Bradford.—A new electric lighting installation is being fitted in the old portion of the Town Hall by the Bradford Electrical Co. There will be about 380 lamps in all, and a complete system of telephone intercommunication is also being provided.

Braunton (Devon).—The Parish Council have adopted the electricity supply scheme drawn up by Messrs. Crompton & Co.

Hitherto oil has been used for street lighting, but under the arrangement with Messrs. Crompton electric current will be supplied for street lighting at 2·15d. per unit, and a supply will also be available for private lighting at a moderate charge.

Burnley.—The Electricity committee have entered into an agreement with Brierfield Council as to the working of the tramways in Brierfield for 14 years from March 31, 1909.

Burnley Corporation will supply the power and lay a cable from the electricity works to Brierfield Centre at a cost of £1,800. The rent of the lines in Brierfield will be £1,000 a year.

Colchester.—The electrical engineer has been given authority to suspend or dismiss any member of his staff if he deems it necessary, the circumstances to be fully reported to the ensuing meeting of the Council.

Colwyn Bay.—An inquiry was held last week into the application of the Council for sanction to borrow £2,300 for extending their electric supply cables to Old Colwyn.

The electrical engineer (Mr. A. R. TUDMAN) stated that there was a reasonable prospect of extensions to Old Colwyn being remunerative, especially as the trustees of the new sanatorium, which is being built in connection with the Cheadle Hulme asylum, were arranging to take current for lighting.

The inspector (Mr. H. Ross HOOPER) suggested that no further loans should be obtained for services or meters, but that for the future these should always be paid for out of revenue as required. He also stated that before any additional loans would be sanctioned the Board would require the amount borrowed on an engine now scrapped to be deducted from the capital account. He advised that £1,000 should be obtained for further expenditure on mains to render applications to the Board for small loans unnecessary.

Conciliation and Arbitration Boards.—The Labour Department of the Board of Trade have issued their report on strikes and lock-outs and on conciliation and arbitration boards in the United Kingdom in 1909. The present is the 22nd annual report, and in a prefatory memorandum the Secretary of the Department (Mr. G. R. Askwith) states that

Although the number of workpeople involved in disputes in 1909 (300,819) was the highest recorded since 1894, the working time lost was comparatively small. The aggregate duration of all the disputes in progress amounted to about 2,750,000 working days, which was little more than one-fourth of that recorded in the previous year, and was well below the average of the 10 years 1899-1908. Spread over the whole industrial population, exclusive of agricultural labourers and seamen, the working time lost in 1909 averaged only about one quarter of a day per head. The coal-mining industry was more affected than any other trade, accounting for 90 per cent. of the total number of workpeople affected and 78 per cent. of the time lost.

Questions of wages accounted for only 25 per cent. of the workpeople directly affected, while questions of hours of labour involved 51 per cent., largely due to differences arising out of the adjustment of working hours after the passing of the Coal Mines Regulation Act. Methods of conciliation and arbitration continue to be more and more generally employed, the number of disputes settled by these means in 1909 being the highest recorded. The number of cases settled by joint boards composed of employers and workpeople showed a considerable increase, due to the activity of the boards formed in 1908 for the principal railways of the United Kingdom. During the year the machinery for conciliation was extended by the formation of boards for the printing trades of the United Kingdom, the Birmingham brass trades, the pottery trade in Scotland and the London County Council tramway workers. Of the 59,945 workpeople directly involved in disputes settled by conciliation or mediation 56,882 were in the coal-mining industry, and 847 in the metal, engineering and shipbuilding trades. The proportion of workpeople involved in disputes beginning in 1909 which were settled by arbitration was 11 per cent., compared with 3 per cent. in the previous year. The proportion of workpeople whose disputes were settled by conciliation or mediation was 35 per cent., as compared with 67 per cent. in 1908. Of the cases considered by permanent boards 698 were settled by the boards or their committees and 327 by umpires or arbitrators appointed by them.

Cookstown (Ireland).—At the last meeting of the Council a motion to adopt a municipal electricity supply scheme was rejected, but it was decided to ask Messrs. Adair, who have an independent generating plant, if they are prepared to supply electricity for private and public lighting, and on what terms.

Dalkey.—The Council have decided not to apply for a provisional order, but are disposed to make arrangements with the Dublin United Tramways Co. for supply of electricity if the company obtains powers.

Dunfermline.—Treasurer Harley reported on Monday an interview with the Board of Trade on the proposal to transfer the Corporation's electric lighting order to the Fife Electric Power Co.

The Board objected to a proposal of the company that in 30 years the Council could take over consumers up to a certain limit, the company retaining the larger power consumers. The Board's objection was to a partial transfer of the business. A further conference is to take place.

East Molesley.—The electric light installation at the fire station is to be extended.

Edinburgh.—The question of the disposal of the surplus (£7,300) on the past year's working of the electric supply department was considered by the Electric Lighting committee on Tuesday.

A communication was considered from the consulting engineer (Sir Alex. Kennedy), in which he recommended to the committee, in view of the resolution of the Council to replace by newer and more economical machinery part of the plant at Dewar-place station, that the surplus be devoted to wiping off the unpaid portion of the original cost of the old machinery. That cost was £21,000, and of that amount about one-half had been paid off by the ordinary operation of annual payments towards sinking fund. The committee agreed that the balance be so applied.

In connection with the extension of plant at Dewar-place, the committee unanimously approved of specifications for the new work, and agreed to advertise for estimates. Sir Alex. Kennedy stated that he hoped to produce a type of cooling tower which would not in any way be detrimental to the amenity of the district. The cost of the new plant, consisting of high-pressure turbines and of cooling towers, will be £45,000, and the work will be completed by next autumn.

Electrical Exhibition.—Mr. H. D. Wilkinson, 4, Queen-street-place, London, E.C., advertises for novel appliances for consumers for lighting, heating and power, required for a colonial electrical exhibition.

Fair Wage Dispute.—The next engineering central conference will consider a novel reference from Manchester.

Manchester Electricity committee recently recommended the acceptance of a particular tender, and the City Council was about to adopt the recommendation when the District committee of the Federation of Engineering and Shipbuilding Trades objected, on the ground that the tenderers did not conform to the local fair-wage clause. As a federated firm the contractors took up the position that if the conditions in their shops conformed to the terms of agreement the men had no occasion to complain. Of the 17 affiliated trades six are covered by the terms of agreement. But the local representatives of the half-dozen proceeded to insist for their own part that the fair-wage clause of Manchester Council was better than the provisions of the terms of agreement.

Farnworth (Lancs.).—The public library is to be wired.

Felixstowe.—The L.G. Board have sanctioned the borrowing of £4,260 for the purchase of a Diesel engine and other plant for the electricity works, the loan to be repaid in 15 years.

Application has been made for sanction to a loan of £3,000 for mains extensions, &c., during the next three years.

Glasgow.—A new tramway route, between Hyndland to Alexandra Park, was opened for traffic on Monday.

Glastonbury.—Messrs. J. & W. Purves propose to apply for a provisional order, and a special meeting of the Council will be held to consider the draft order submitted by the firm.

Greenock.—The Admiralty have informed the Corporation that the supply of electricity required for the torpedo factory at Battery Park will be equal to about 400 kw., or double the original contract.

Hackney (London).—The showroom of the electricity department is to be opened on 22nd instant.

In connection with the opening of the showroom two additional clerks are to be permanently engaged. A lady demonstrator and two canvassers are also to be employed, their appointments to be temporary so that their capabilities be ascertained. The lady demonstrator will be engaged in the kitchen of the showroom for exhibiting the use of the cooking apparatus. In addition to her salary she will be allowed commission on sales effected by her in the showroom. The fitting up of the premises has been carried out by Messrs. Maple & Co. at £427. 13s. 6d.

Tenders are to be invited for the supply of 80,000 pairs of white arc lamp carbons.

Harbour Lighting.—Whitehaven Harbour Commissioners have agreed with the local Council to light the harbour with Osram lamps for five years at £230 per annum.

Heanor.—The engineers of the Notts & Derbyshire Tramways Co. are making surveys and preparations for the construction of tramways which will connect Heanor with Nottingham, Ripley and Derby.

Hendon.—At the last meeting of the Council it was reported that Major Pringle, of the Board of Trade, had inspected the route over which it was proposed that rail-less cars should run, and a map of a section of the proposed route is to be forwarded to the Board of Trade.

Manchester.—The City Council adopted on Tuesday a recommendation of the Tramways committee to make arrangement with the general manager of the tramways, Mr. J. M. McElroy, under which he is to agree to remain in the service of the Corporation for five years from the present time, and his salary of £1,000 per annum is to be increased by annual sums of £50 up to £1,250. The first annual increase takes effect from Jan. 1, 1910.

Marconi Marine Progress.—A circular issued by the Marconi International Marine Communication Co. is an interesting document in several ways, and particularly as showing the large number of marine telegraph stations controlled by, or operated in connection with, the company. The list gives a good idea of the number of these stations at the time when it was issued, but it is even more interesting in the case of the copy we have under notice from the large number and additions which have been interpolated since the list was first issued. Page after page is filled with the names of vessels in all the leading steamship lines, and the list indicates that the time will soon come, even without legislation, when all vessels, except perhaps those which are purely cargo carriers, will automatically fall into line and be equipped with wireless apparatus.

Marylebone (London).—The latest of the well-known "Borough" series of Guides deals with St. Marylebone, and is in no way behind its predecessors in illustrations and general get up. Photographs of Oxford-street at night and of the interior of the borough generating station are given, while opportunity has been taken by Mr. A. H. Seabrook of bringing before his readers the great advantages attendant on the use of electricity for all purposes. A very good description of the generating station is included.

Municipal Wiring Bill.—In addition to the Local Authorities already published, the Corporations of Burton-on-Trent, Luton, South Shields and Nelson have decided to support financially the proposal of the Municipal Electrical Association to promote a bill to confer powers upon local authorities for wiring premises, &c., and Oban, Redditch and Neath Councils will give it their moral support.

Newport (N.B.)—Recently the Council refused to allow the Tayside Electric & Gas Light Co., of Wormit, to extend their electric supply mains to Newport, but a number of influential residents have petitioned the Council to grant the company the necessary permission.

Digitized by Google

Norwich.—The Council are recommended by the Electricity committee to apply for sanction to a loan of £18,790 (instead of £17,783, decided upon by the Council on March 15 last) for mains, services, exhaust steam turbine, pipes, centrifugal pump, balancer, coal elevator, &c.

Poplar (London).—The supply network in Gale-street is to be strengthened at a cost of £795.

32 street gas lamps are to be converted to electric lighting at a cost of £128. The charge for gas, attendance and mantles now amounts to 58s. per lamp per annum; and the charge for current, renewals and attendance when the lamps are converted to 50 c.p. electrics will amount to £2. 11s. 4d., or a saving of 6s. 8d. per lamp annually (equal to 11½ per cent.), which will gradually increase as the life of metal filament lamps is improved, and the cost reduced.

Presentations.—On his marriage Mr. Herbert Jackson has been presented by Manchester tramway traffic department staff with an oak clock and by the Tramway Employé's Athletic Society (of which he is hon. sec.) with a bookcase and bureau.

Bournemouth tramway staff have presented a gold watch and chain to Mr. J. H. Chick, station engineer, who is leaving for Ceylon.

The staff of the Bath Electric Tramways (Ltd.) have presented a Chippendale grandfather's clock, and the engineering staff a recording barometer to Mr. W. E. Hardy, manager and engineer, on his marriage. The directors of the company have also presented Mr. Hardy with a silver salver.

Sevenoaks.—The Council, who have decided to proceed with an electricity supply scheme, have appointed a sub-committee to select a suitable site for a generating station. Messrs. Mordey & Dawbarn are consulting engineers to the Council.

Sheffield.—The Electric Light committee are inviting tenders for additional generating plant for the Neepsend power station.

A loan of £2,500 is required for the purchase of electric motors to be let on hire.

Swansea.—The local tramways company is about to double the whole of its line on the Morriston section, from the Imperial to the Duke Hotel.

Watford.—At the last meeting of the Council the clerk stated that a communication had been received from the L.G. Board enclosing five sanctions for electric lighting loans.

Coun. Goodrich, chairman of the Electricity committee, said he objected to the letter being read. There were some comments in the letter concerning public lighting and suggesting that the Council should look further into the question of using gas. The answer to that was that 150 street lamps had been converted to metal filament lamps and between 30 and 40 were being changed. No good purpose would be served by making the letter public.

Coun. Rider said he was opposed to municipal trading on principle, but it would be absurd for the Council to reveal their secrets to their commercial rivals.

Mr. J. Gowers, hon. sec. of the Watford Tradesmen's Association, wrote enclosing resolutions which had been passed by that body, deprecating any further delay in carrying out the original tramway scheme and opposing a railless system.

The Tramways committee recommended that the Council appoint delegates (on condition that there was no cost to the Council) to investigate, with representatives from the County Council, the systems of railless traction in operation in Berlin and Vienna. This report was considered in committee.

Wells.—The City Council have been informed by Messrs. J. & A. Purves of their intention to apply for a provisional electric lighting order.

West Bromwich.—An unopposed inquiry was held on Friday into the application of the Corporation for sanction to borrow £11,386 for extensions of the electricity undertaking.

The Town Clerk said the loan was for an extension of the plant at the electricity works, to enable them to supply the Spon-Lane district during the winter.

The Inspector (Mr. H. Ross Hooper) said he was in doubt as to the advisability of spending nearly £12,000 in extending the undertaking upon the direct-current system, and he suggested that the Corporation should consider whether it would not be the wiser to adopt the alternating-current system, under which electricity for power could be generated at a cheaper rate. He pointed out that the low-tension direct-current system was not being extended in the country for power purposes. At West Bromwich they had gone on very well with their electricity undertaking up to the present, but it was for them to consider whether the money which they were now going to spend for power users would not be better spent on a different system. He suggested if they were prepared to spend nearly £12,000, whether it would not be wise for them to see if the alternating-current system was not the more suitable for the supply of their district. It was for the Council to consider the position. Power was no use unless it was cheap, and the question was whether they were going to have a cheap supply in future. If so, then the supply would be the cheapest if the district was such that the alternating-current system could be introduced. He did not want them to find out two or three years hence that they would have been better off if they had put in and extended the alternating-current instead of the direct-current system.

The borough electrical engineer (Mr. W. A. Jackson) said they had considered that question carefully, and they thought it advisable at present to go in for a direct-current plant.

West Ham—*Correction.*—The amount of the loan recently sanctioned by the L.G. Board for extensions of the electricity undertaking was £53,500, and not £55,000, as stated in our last issue.

Willesden.—The Council will supply electric current to Mr. J. B. Mulholland's new theatre at 1d. per unit between midnight and 6 p.m. and at the ordinary lighting rates between 6 p.m. and midnight, provided a minimum consumption of 20,000 units a year is guaranteed.

Wireless Telegraph Notes.—A disaster happened to one of the huge train-ferryboats operating on Lake Michigan on Friday last week, which, but for timely warning by wireless, would have resulted in a larger loss of life than actually occurred. The ferry was 350 ft. long and carried the trains of the Père Marquette Railroad across the Lake. In the train and ferry at the time of the disaster 62 persons were being carried across; 29 were drowned, but the arrival of assistance, due to the wireless message, caused the lives of 33 others to be saved. The wireless operator on the ferry, who stuck to his post, was amongst the drowned.

It is announced that the Marconi International Co. has secured an order for equipping 11 Turkish battleships with wireless installations, together with a coast station to be situate at San Stefano.

The leading public journals are taking advantage of the equipment of the popular lines of steamers with wireless telegraph apparatus to institute a general scheme of receiving and publishing news from ships at sea, and it seems likely the arrangement will become general.

The most important matter in relation to wireless telegraphy just now is its effectiveness in establishing intelligible communication with submarine vessels. The naval experiments which are being conducted in British waters at the present time, it is stated, although of little comparative value so far, have improved so rapidly that much greater success in the early future is anticipated.

Workhouse and Infirmary Lighting.—Canterbury Guardians have decided to substitute electric for gas lighting at the workhouse and infirmary.

The Lighting committee went into the matter fully and obtained a report from the city electrical engineer (Mr. C. A. Blaschek) who estimated the cost of the wiring at £165. This sum would include replacing all lights at present in existence, besides lighting several places which have no light, but where a light is required. In all the installation will be equivalent to 366 8 c.p. lamps. The gas account for the last financial year was £216, but £36 of this was for cooking and heating. The estimated cost of electric lighting would be £100, so that by adopting electric lighting they would be saving £80 a year, and would have a better light.

The L.G. Board have anthorised Tipperary Guardians to borrow £2,280 for electric lighting plant, the loan to be repaid in 20 years.

The new infirmary, Newton Abbot, is to be wired.

COLONIAL AND FOREIGN NOTES.

Argentina.—Paquet y Cia. have obtained a Government concession for the construction and working of an overhead electric conveyor across the Riachuelo river and a six months' option to construct a second conveyor.

Austria-Hungary.—Vienna-Neustadt Municipality have obtained powers to borrow £23,600 for erection and equipment of electricity works.

Brussels Exhibition Awards.—The following are amongst the awards to British exhibitors at the Brussels Exhibition, as set out in "The Times" yesterday (Thursday):—

Class 15.—Mathematical and Scientific Instruments; Coils, &c. *Grand Prix.*—F. Darton & Co., Kelvin and James White, W. F. Stanley & Co. *Silver Medal.*—Gambrell Bros., John J. Griffin & Sons, Townson & Mercer.

Class 19.—Steam Plant. *Grand Prix.*—E. Green & Son, J. Hopkinson & Co., Marshall, Sons & Co., J. & H. McLaren, Ruston, Proctor & Co. *Diploma of Honour.*—Underfeed Stoker Co., G. & J. Weir. *Gold Medal.*—Holden & Brooke, National Gas Engine Co.

Class 21.—General Machinery. *Grand Prix.*—Appleby Crane & Transporter Co., J. & H. McLaren, Hans Renold (Ltd.), R. Waygood & Co. *Diploma of Honour.*—Marryatt & Place, Reavell & Co., G. & J. Weir. *Gold Medal.*—Aerograph Co., Coventry Chain Co., Lacy Hulbert & Co., Ruston, Proctor & Co., Sturtevant Engineering Co.

Class 23.—Mechanical Production and Utilization of Electricity. *Grand Prix.*—Kelvin & James White, Morgan Crucible Co., C. A. Parsons & Co., Reflector Synd., R. Waygood & Co. *Diploma of Honour.*—Marryatt & Place. *Gold Medal.*—Lancashire Dynamo & Motor Co.

Class 24.—Electro-Chemistry. *Gold Medal.*—John J. Griffin & Sons, Reflector Synd.

Class 25.—Electric Lighting. *Gold Medal.*—Faraday & Son. *Bronze Medal.*—J. Dugdill & Co.

Digitized by Google

CLASS 27.—MISCELLANEOUS APPLICATIONS OF ELECTRICITY. *Grand Prix.*—Kelvin & James White, R. W. Paul. *Diploma of Honour.*—Gambrell Bros., Nalder Bros. & Thompson, Synchronome Co.

CLASS 87.—APPLIED CHEMISTRY AND PHARMACY. *Grand Prix.*—Johnson, Matthey & Co., Thermal Synd.

The Cambridge Scientific Instrument Co. were placed *hors concours* in Class 15 (Mathematical and Scientific Instruments).

Italy.—The Società Anon. Tranvia Elettrica Valle di Gressoney is to be formed with a capital of £60,000, to construct and work an electric tramway from Pont S. Martin to Gressoney la Trinité.

Jersey Telephone System.—The Jersey Chamber of Commerce has petitioned the States to acquire the present National Telephone system, and the proposal has been referred to the Public Works committee.

Perth (W.A.) Tramway Strike.—The strike of the tramway employes on the Perth (W. Australia) tramways has been settled.

South Africa.—Electrical plant is being installed in the Utrecht (Natal) Colliery for light and power purposes and also for lighting the town of Utrecht.

Spain.—The August report of the British Chamber of Commerce for Spain says there is an opening in Madrid for electric pumps for raising water to tanks on the roofs of houses, as building is proceeding rapidly and many of the houses are at such an elevation that the pressure in the mains is not sufficient to raise the water above the first floors.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Ayr.—The annual report of the tramways manager (Mr. W. Grant) for the year ended May 15 shows that 3,588,628 passengers were carried (decrease 21,909), and the total car-mileage run was 387,704 (decrease 2,401).

The total revenue was £15,007. 8s., a decrease of £73. 19s. 7d., and after paying expenses and capital charges the net balance was £2,491. 0s. 6d., of which £1,962. 0s. 10d. was carried to depreciation fund, and £528. 19s. 8d. to burgh assessment.

The report of the burgh electrical engineer (Mr. R. Marshall) stated that the number of equivalent 30-watt lamps connected was 68,250, an increase of 6,558. The units generated were 1,763,835, an increase of 77,902. The capital expended was £102,329, an increase of £1,713, and the sinking fund now amounts to £24,060. Mr. Marshall states that Ayr has now a larger number of electricity consumers per 1,000 of population than any other city or town in Scotland. The increase in the number of units sold for private lighting was small, in spite of the fact that a larger number of additional lamps were connected than in some previous years. This was undoubtedly due to the extended use of metal filament lamps. The revenue from private lighting was £8,150; power, £804; public lighting, £3,454; tramways, £2,237; other sources £221, or a total of £14,867, an increase of £1,020. The expenditure amounted to £6,753, leaving a gross profit of £8,113. After paying interest and sinking fund charges (£5,669), there was a surplus of £2,444, which exceeded the surplus of the previous year by £1,020 and was the largest surplus made by the department. Of the surplus £1,200 has been allocated to relief of rates, and the remainder to reserve fund, which now amounts to £1,777. Mr. Marshall is of opinion that all future surplus revenue should go to augment the reserve fund until it reaches a sum sufficiently large to ensure the financial stability of the undertaking.

Both reports have been approved by the Corporation.

Bermondsey (London).—The capital expended on the electricity department at March 31 was £168,134, an increase of £13,024 during the past year.

Revenue from sale of current was £15,831 nett, and total receipts £21,744. Cost of generation was £6,397 (including £2,544 for coal and £1,229 for calorific power derived from the dust destructor), and total expenses £10,948, leaving gross profit £10,796. After providing for interest, instalments of money repaid, &c., and taking into account balance from last account there was a deficit of £1,277. 3,612,558 units were generated, and 3,183,691 units sold (2,626,130 to private consumers and 557,561 to public lamps). There are 175 arc lamps, 217 110-watt, 49 Nernst and 2 carbon filament lamps for street lighting. The total maximum supply demand is 1,445 kw. The estimates for 1910-11 put the anticipated net profit at £666, against £500 in 1909-10.

Cardiff.—The city treasurer (Mr. John Allcock) has issued the accounts of the city for the year ended March 31.

The traffic receipts of the tramways department were £114,306, against £110,489 in 1908-9. The revenue from advertising increased by £784 to £1,879. The revenue for energy supplied to electric lighting account increased from £12,120 to £14,188, the total income being £130,565, increase £6,714. On the expenditure side there was an increase of £845. The gross profit was £56,187, against £50,318; the loan charges amounted to £45,394, and the net profit was £11,032 (an increase of £5,077), of which £6,037 was transferred to depreciation fund and £4,094 to reserve. The total capital expenditure was £778,017, and the net liability £645,024. During the year capital was increased by £45,624.

On the electricity supply department the capital expended was £268,429, an increase of £5,067 during the year. The excess expenditure on capital account is £9,254. The past year's income was £43,195, an increase of £1,219. The expenditure amounted to £28,108, an increase of £2,255, due mainly to the increased supply of energy obtained from the tramways department. The gross profit was £15,087, compared with £16,122. The loan charges amounted to £16,211, leaving a net deficit of £1,124, but there had, on the other hand, been extraordinary items of expenditure, and, taking these into consideration, the surplus for the year was £94.

SPECIAL NOTICE.

NOW READY.—Vol. LXIV. of "THE ELECTRICIAN" (1,085 pages), bound in strong cloth. Price 17s. 6d.; post free, 18s. 6d. Now ready. Cases for Binding. Price 2s.; post free, 2s. 3d.

A complete set of "THE ELECTRICIAN" can be supplied. A number of odd volumes and some odd old back numbers, to help in making up complete sets, are also available.

Handsworth.—The accounts of the electric supply department for the year ended March 31 show a total annual income of £7,813 (against £6,777), including £3,044 from sale of current for private lighting, £1,386 for power, £1,843 for traction and £1,490 for public lighting.

Total expenditure was £3,806, leaving gross profit £4,007, against £3,265. Interest on loans (including tax) was £2,653 and repayment of loan £1,580, leaving (after taking into account £434 from 1909) a balance of £208. The total capital expenditure is £73,478, an increase of £3,076 during the past year. 851,430 units were sold (721,254 to private consumers and 130,176 supplied to the public lamps), against 731,465 in 1909. There are 124 arcs and 247 incandescent lamps for public lighting, and the total maximum supply demanded was 602 kw., against 469 kw.

In the report of the chief engineer and manager (Mr. F. A. Nixon) it is stated that the most prominent feature of the past year was the large increase in the number of consumers connected to the mains—131 against 87 in 1909. Owing to the extended use of metal filament lamps the units consumed had not increased in the same ratio. Efforts are being made to popularise the use of electricity for domestic purposes, and a considerably increased demand for cooking and heating is expected. The hiring and purchase schemes, for which a small loan was sanctioned, have been put into operation, and many residents have availed themselves of the facilities offered. The total works costs per unit sold was 0·67d. (against 0·73d.), the coal cost being 0·28d. (against 0·33d.)

Newcastle-on-Tyne.—The annual report of the general manager of the tramways (Mr. E. Hatton) states that the gross receipts for the year ended March were £209,676, against £209,541.

Working costs were £115,920, against £121,076. Gross capital expenditure (exclusive of public lighting) is £1,170,234, or with public lighting, £1,184,644. Traffic revenue amounted to £203,339, against £203,302, other revenue amounting to £6,337. Operating costs (including lighting) were £117,593, or 56·08 per cent. of total revenue. Gross profit was £92,081 (7·77 per cent. per annum on the average capital), compared with £86,931 (7·35 per cent.). The total amount repaid (by sinking fund instalments, &c.) was £262,144. After contribnting £1,538 to relief of rates, against £1,551, there was a surplus of £15,121 (against £7,558). At the end of the financial year the total of reserve and renewals fund was £72,257 against £62,699. The car-miles run were 4,430,085 against 4,289,997, and the number of passengers carried was 44,516,958, against 44,439,282.

Peterborough.—The total receipts of the electricity department for the year ended March were £7,098. 2s. 1d.

Total expenses were £3,872. 5s. 11d.; and after allowing for bad debts, paying interest and repayments of principal (£3,524. 15s. 5d.), costs of arbitration case with local Electric Traction Co. (£1,016), and for works of extensions, &c., not charged to revenue (£476), the total deficit was £1,801. 1s. 6d. Under the agreement with the Corporation, the Traction Company have the right to demand every five years a revision of the charges for electricity consumed, and as the Corporation and the Company were not able to agree, the case was referred to an arbitrator. That gentleman decided in favour of the Corporation's charge for electricity, but mulct the Council in the costs.

Swindon.—There was a net profit of £717 on the past year's working of the electricity undertaking.

The income showed an increase of £328 over 1909; the working expenses were £4,827 (decrease £992), interest £1,821, sinking fund £1,795, and contribution to reserve £443. There was an increase of revenue from public lighting of £470, and a decrease of £325 on current supplied to the tramways. There were 838 consumers on March 31, and this number had increased to 862 on August 15, the equivalent 8 c.p. lamps being 32,489 and 32,936 respectively. There is also 371¼ H.P. of motors connected. There was a large decrease in the expenses, coal being 0·08d. less per unit sold.

Warrington.—The total revenue of the tramways department for the year ended March was £20,169, including £19,862 traffic revenue.

Total working expenses were £11,406 (6·281d. per car-mile), and gross profit £8,764 (4·827d. per car-mile). Interest was £3,007 and sinking fund £3,007, leaving net profit £2,750, of which £1,000 was applied to relief of rates and £1,750 carried forward. The gross capital expended was £102,128, the same as in 1909. 5,206,980 passengers were carried, and 435,774 car-miles run, and 528,139 units of electric current (1·212 per car-mile) were consumed.

TRADE NOTES AND NOTICES.

TENDERS INVITED.

Tenders are invited by EDINBURGH Corporation for three steam turbines and d.c. generators, each of 1,200 kw., and condensing plant and interior parts of cooling towers, for their Dewar-place electricity station. Copies of specification, forms of tender, &c., from the engineer, Mr. F. A. Newington, Dewar-place, Edinburgh, and specifications, conditions and drawings may be seen at, but not obtained from, the offices of the consulting engineer, Sir Alexander Kennedy, 17, Victoria-street, London, S.W. Tenders must be delivered at the office of the town clerk, Mr. Thomas Hunter, W.S., City-chambers, Edinburgh, by Monday, Oct. 10. See also an advertisement.

The Electric Light committee of the City of SHEFFIELD invite tenders for supply of steam turbine alternator, exciter, condensing plant, pumps and other accessories, and three water-tube boilers, economisers, induced draught fan, steel chimney, &c. Specifications, forms of tender and general conditions from the general manager and engineer, Mr. S. E. Fedden, Corporation Electric Supply Department, Commercial-street, Sheffield, where tenders are to be delivered by 10 a.m. of Friday, Sept. 30. See also an advertisement.

The Directors of the METROPOLITAN RAILWAY Co. are prepared to receive tenders for the supply of general stores during 12 months ending Oct. 31, 1911. Forms of tender (No. 13, electric wires and cables; No. 14, electric lamps, carbons, switches, fuses, telephones, coils, &c.; and No. 15, insulating materials) from the Secretary, 32, Westbourne-terrace, London, W., on or after Sept. 23. Tenders to the Secretary by 10 a.m., Oct. 3. See also an advertisement.

Tenders are invited for supply of telegraph and telephone cable (schedule No. 284) and insulators (schedules Nos. 373 and 374) to the Postmaster-General's Department, VICTORIA. Tender forms at the Commonwealth Offices, 72, Victoria-street, London, S.W. See also an advertisement.

The Electricity and Tramways committee of the County Borough of NEWPORT (Mon.) invite tenders for material required for the extension of the works in hand, including rubber cables of various sizes, single-phase l.t. and h.t. paper lead-covered cable and e.h.t. cable, welded steel, or solid drawn steam pipes, valves and cast-steel tees, rolled steel girders, c.i. and w.i. switch gallery railing, two c.i. stanchions, motor starters and other switchboard apparatus (l.t.) and c.i. flanged water pipes. Particulars from the borough electrical and tramways engineer (Mr. H. Collings Bishop). Tenders must be delivered to the Town Clerk, Town Hall, Newport, Mon., by first post Tuesday, Sept. 20.

By command of the POSTMASTER-GENERAL tenders will be received until noon, Monday, Sept. 26 for supply of Swedish, Norwegian, Finland or Russian red fir telegraph poles to be delivered at certain ports in the United Kingdom. Forms of tender from the Controller of Stores (Mr. G. Morgan), Stores Dept., G.P.O., 17-19, Bedford-street, London, W.C.

The POSTMASTER-GENERAL also requires tenders (by noon Sept. 26) for creosoting, &c., telegraph poles. Forms of tender, &c., from the Controller of Stores, 17-19, Bedford-street, London, W.C.

BIRMINGHAM electric supply department want tenders by Sept. 30 for 12 months' supply of coal (about 78,000 tons) to the generating stations. Further particulars from the City Electrical Engineer.

RHYL Council invite tenders for 12 months' supply of fuel oil from Oct. 1. Tenders to the Clerk by 26th inst.

Tenders are invited up to noon Oct. 17 for the supply of telegraph and telephone instruments and material (as per schedules 1 to 9) to the Postmaster-General's Department in TASMANIA. Tender forms and specifications at the office of the High Commissioner, 72, Victoria-street, London, S.W.

The Deputy Postmaster-General, MELBOURNE, will receive tenders until 3 p.m. Oct. 18 for supply of 23 miles of telephone cable (specification 284) and 500 composition insulators (specification 374) and until 3 p.m. Oct. 25 for 10,000 Cordeau insulators (schedule 373). Specifications, &c., from 72, Victoria-street, London, S.W. Local representation is necessary.

Tenders are invited up to Oct. 5 for the supply of 5,000 porcelain insulators to the Postmaster-General's Department in NEW SOUTH WALES. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W.

Tenders are invited up to Oct. 4 for the supply of telegraph and telephone insulators to the Postmaster-General's Department in all the States of the Commonwealth of AUSTRALIA. Tender forms at the Commonwealth Offices, 72, Victoria-street, London, S.W.

Tenders are invited up to Oct. 4 for the supply of telegraph and telephone material to the Postmaster-General's Department in VICTORIA. Forms of tender, &c., from the Commonwealth Offices, 72, Victoria-street, London, S.W.

Tenders are invited up to Sept. 27 for the supply of electric lamps to the Postmaster-General's Department in VICTORIA. Forms of tender, &c., from the Commonwealth Offices, 72, Victoria-street, London, S.W.

Tenders are invited up to Sept. 20 for the supply of telegraph and telephone material to the Postmaster-General's Department in VICTORIA (Australia). Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W.

ADELAIDE (S. Australia) Municipal Tramways Trust want tenders by Oct. 11 for supply of 1,750 tons of tramrails, 150,000 dogspikes and 1,200 tiebars and by Oct. 18 for bonding material.

Tenders will be received by the Minister of Telegraphs, G.P.O., WELLINGTON, N.Z., up to noon Dec. 15, 1910, for supply and erection of installations of wireless telegraphy at or near Doubtless Bay, Gisborne, Cape Farewell, Sumner (near Christchurch) and Bluff. Specification, conditions, &c., at the office of the Superintendent of Electric Lines, G.P.O., Wellington, and the office of the High Commissioner, 13, Victoria-street, London, S.W., and also from Messrs. R. W. Cameron & Co., 23, South William-street, New York, and Mr. H. Stephenson Smith, 244, California-street, San Francisco, Cal. Tenders must state the name of the country in which the apparatus, &c., will be manufactured.

The Ministry of Public Works, CAIRO, require tenders for electrical installations and refrigerating plant for the lunatic asylum in course of construction at Khanka. Specifications from the Chief of the Administrative Service, Ministry of Public Works, Cairo. Stamped paper for tenders is obtainable from Mr. A. L. Webb, Westminster, S.W. Tenders by noon Oct. 20. Legal domicile at Cairo is necessary in the case of this contract, and to obtain temporary domicile British firms must, before electing such domicile, formally advise the Consulate at Cairo of intention to do so, formally authorise the Consulate on their behalf and inform the Consulate of the address to which documents should be forwarded.

Tenders are wanted by noon Oct. 31 for supply and erection of machinery, &c., for electricity supply and water supply systems for the town of BENI-SOUEF (Egypt). Particulars may be obtained from Mr. A. L. Webb, C.M.G., Queen Anne's-chambers, London, S.W. Local representation is necessary.

The Turkish Ministry of Commerce and Public Works want tenders by Oct. 28 (Nov. 10) for a concession for the construction and working of electric tramways in CONSTANTINOPLE and suburbs. A deposit of £13,500 (sterling) is required with each tender. Local representation is essential. Copy of specification (in French) may be seen at 73, Basinghall-street, London, E.C.

MOSTAR (Austria-Hungary) Municipality require tenders by Oct. 1 for the installation of electrical generating plant. Specification (in German) can be seen at 73, Basinghall-street, London, E.C.

The "North China Herald" states that SHANGHAI electricity department require tenders by noon Oct. 10 for supply of electric heating and cooking appliances, and by noon Oct. 20 for 10,700 carbon and 15,000 metal filament lamps. Specifications from the Electricity Works, 31, Fearon-road, Shanghai.

TENDERS RECEIVED AND ACCEPTED.

Stockport Council have accepted the following tenders:—

Dussek Bitumen Co., bitumen, £5. 10s. per ton; Morgan Crucible Co., carbon brushes; H. Hollingdrake & Son, 50 draw chairs, 16s. per cwt., iron tubing, nuts, bolts, &c.; J. G. Bradwell, iron castings; British Insulated & Helsby Cables, overhead line materials; Wilkinson, Heywood & Clarke, paints and varnish.

Bradford Corporation are recommended to accept the following tenders for electrical equipment for the Technical College:—

Bruce, Peebles & Co., motor-alternator set, £190; British Westinghouse Co., shunt machine set, £75; Greenwood & Batley, series motor, £29; Lancashire Dynamo & Motor Co., single-phase commutator motor, £53; Phœnix Dynamo Mfg. Co., motor converter set, £105.

Bristol Electrical committee have recently let the following tenders:—

City Glass Co., supply of arc lamp globes for 1910-1911 (£38. 15s.); Siemens Bros.' Dynamo Works, supply of three-phase, e.h.t., l.t. and d.c. switchgear at Dock sub-station (£204. 15s.); Slaughter & Bray, constructional work, &c., at the Exchange, in connection with the offices, show-rooms and stores scheme (£1,372).

The contract for the complete electrical equipment of the Palladium Theatre of Varieties (Argyll-street, London) has been placed with Messrs. Siemens Brothers Dynamo Works, who have sublet the wiring work to Messrs. Rashleigh Phipps & Co.

Digitized by Google

Walsall Council have accepted the tender of the British Westinghouse Co. for supplying and fixing rotary converters and switchgear at £1,145, and that of Callender's Co. for supplying and laying h.t. mains at £5,026.

Bristol Electricity committee have accepted the tender of the British Westinghouse Co. for two three-phase 3,000 kw. turbo-alternators at £25,290.

Elland Council have accepted the tender of the Gath Electrical Engineering Co. for tantalum and sun lamps for a year; and that of Sykes & Sugden for 12 straight through boxes.

Whitehaven Corporation has placed an order with Ed. Bennis & Co. for supply of four "Bennis" stokers and self-cleaning natural draught furnaces for B. & W. boilers.

Lowestoft Council have accepted the tender of the Standard Cable Mfg. Co. for a mile of overhead trolley wire at £67, and that of Walter Scott (Ltd.) for 50 tons of tramway rails at £6. 15s. per ton.

Skipton Council have placed an order with J. Banks for an electric lighting installation (including gas engine and dynamo, wiring, fittings, &c.) for the Town Hall.

Stretford Electricity committee have accepted the tender of Bertram Thomas for a battery panel at £36. 15s.

Gosport Council have accepted the tender of W. M. Walters for wiring the Council offices at £56.

BUSINESS NOTICES.

Messrs. Preece & Cardew have made arrangements for Messrs. J. F. C. Snell and S. S. Moore Ede to join them on Oct. 1. Mr. J. H. Woodward, who has been upon the staff of Messrs. Preece & Cardew for the past 12 years, will also become a partner. The partners will be Sir W. H. Preece, K.C.B., F.R.S., A. H. Preece, M.Inst.C.E., J. F. C. Snell, M.Inst.C.E., Llewellyn Preece, M.Inst.C.E., J. H. Woodward, A.M.Inst.C.E., and S. S. Moore Ede, A.M.Inst.C.E. The name of the new firm will be Preece, Cardew & Snell, and the office will remain at 8, Queen Anne's-gate, S.W.

Messrs. Snell & Moore Ede also notify that they have amalgamated with Messrs. Preece & Cardew, and after Sept. 30 all communications for them should be sent to 8, Queen Anne's-gate, Westminster, S.W.

The A.E.G. Electric Co. (Ltd.) are removing to Pembroke House, 133-5, Oxford-street, W. Telegrams: Galvanolon, London; telephone: 8,848 Gerrard.

The Union Electric Co. have transferred their head office to 109, Pitt-street, Sydney, and Mr. E. H. W. Westwood, A.M.I.E.E., has been engaged to control their present Melbourne offices, at 33, William-street.

We are informed that Mr. T. W. Vaughan, who has for the last year acted as works manager to the Vaughan Engineering Installations (Ltd.) has now no connection with the company, and has no authority to act for it in any way.

E.M.F. (Ltd.) have removed to 212-3, Upper Thames-street, E.C., where the business (office, showrooms and stores) is centralised.

The Metallic Seamless Tube Co., Wiggin-street, Birmingham, have made arrangements with the manufacturers to act as wholesale selling agents for "Brimsdown" metal filament lamps. The company will hold stock at their works and at their London and provincial depots.

The London offices of the Rangoon Electric Tramway & Supply Co. have been removed to 3 and 4, Great Winchester-street, E.C.; and Mr. R. L. Spicer has been appointed secretary.

Sale by Auction.—Messrs. Horne & Co., 35, Old Queen-street, Westminster, S.W., will sell by public auction at the Royal Arsenal, Woolwich, on Thursday, 22nd inst., at 11 a.m., unserviceable and obsolete stores, including quantities of iron and steel, brass, copper, gunmetal, lead and antimony alloy, zinc, mixed metal, &c., electric generator, lifting jacks, telegraph and electric light fittings and instruments, 650 electric lamps, 43,450 electric lamp bases, tools, &c. The lots may be viewed at the Royal Arsenal, Woolwich, on Monday, Tuesday and Wednesday, previous to and on morning of sale. Catalogues from the War Office, Whitehall; the Ordnance Office, Tower; and the Ordnance Office, Royal Arsenal, Woolwich. See also an advertisement.

Business for Sale.—A heating, lighting and ventilating engineering business is advertised for sale in another column.

Plant for Sale.—Northampton Electric Light & Power Co., Northampton, advertise for sale two exhaust steam feed water heaters and two battery charging boosters.

Holophane Reflectors.—Messrs. Siemens Bros. Dynamo Works (Ltd.), Tyssen-street, Dalston, London, N.E., will shortly place on the market a series of 18 new prismatic reflectors of the holophane type, specially suitable for metal filament lamps, and more particularly for "tantalum" lamps. These reflectors will be of handsome appearance and of novel design, the prisms thereupon being of a new shape, ensuring great efficiency as well as good appearance. The reflectors will range in price from 3s. to 12s. each, and the larger and more expensive sizes will be suitable for Messrs. Siemens' new "Onewatt" 100 c.p. lamps, as well as for "Onewatt" lamps of higher c.p. which they hope to place on the market shortly.

CATALOGUES, &c.

Dry Cells and Dry Cell Batteries.—Messrs. Siemens Bros. & Co. have issued a new catalogue dealing with this subject which supersedes that brought out in April of this year. The present issue has been re-arranged and the notes on the employment of dry cells for ignition purposes have, to some extent, been rewritten. New illustrations drawn to scale have been employed throughout.

Optical Pyrometers.—Messrs. Siemens Bros. & Co. have also issued a pamphlet dealing with optical pyrometers, in which they describe the principles of construction of their well-known instruments Besides the standard type, a portable pattern has now been listed.

Union Continuous-Current Motors.—In a pamphlet which they have just sent us the Union Electric Co. describe in great detail the various types of continuous-current motors made by them. These include all sizes from ¼ to 50 h.p., and embody the latest improvements in this class of machine.

Benjamin Wireless Clusters.—The Benjamin Electric Co. have sent us a list which contains illustrations and details of their well-known wireless clusters. The various points of these, which allow efficient and cheap wiring fittings to be obtained, should not be forgotten in the coming lighting season.

Moving Coil Instruments.—We have received from Messrs. Elliott Bros. a leaflet giving details of their portable moving coil instruments. The instrument is contained in a wooden box with a flap lid, and seems to be quite suitable for the work it is designed to do.

Tramway Controllers.—We have received from Messrs. Dick, Kerr & Co. details of their new tramway controller which they have just placed on the market. This contains several points of interest, and we shall hope to describe it in more detail in a later issue.

Sealing-In Machines.—The Foster Arc Lamp & Engineering Co. have sent us a pamphlet dealing with a sealing-in machine which they have just introduced for the manufacture of electric incandescent lamps. This machine is being used by them in their own works for the manufacture of metal filament lamps.

Centrifugal Pumps.—We have received from Messrs. Ernest Scott & Mountain a pamphlet giving full details of their well-known centrifugal pumps.

BANKRUPTCIES, LIQUIDATIONS, &c.

The public examination of Fredk. Peacock, electrician, 59, North Station-road, Colchester, took place last week. Liabilities £228, assets nil.

Debtor had carried on electrical installation business in Colchester for nine years, but had never had any business premises. He had done work for Williams & Co. who supplied him with materials for jobs which he did on his own account, and the work he did for them was set off against cost of materials supplied. They claimed £235, but debtor counter-claimed for £85.

James D. M. Morton, electrical engineer, Nettleton-road, Mirfield, has been adjudicated bankrupt.

The discharge of Alfd. Jas. Hollington, electrical engineer, late of 37, Walbrook, London, E.C., has been granted, subject to debtor's consent to judgment for £25.

The discharge of Geo. Kaye Spivey, formerly electrical engineer, of Market-place, Wakefield, and Bradford-road, Batley Carr, is suspended for two years.

A first dividend of 5s. will be payable on Sept. 21 at 4, Castle-place, Nottingham, to creditors of Thos. Louis Callender (formerly trading as the Shamrock Cycle Co.), electrical engineer, late of Grove-place, St. Heliers, Jersey.

A first and final dividend of 3½d. will be payable at 4, Charter-house-square, London, E.C., on Sept. 26, to creditors of Charlotte Rix (trading as or one of the partners of Bridgewater & Wright), electrical engineer, 78, York-road, King's Cross, London, N.

A first and final dividend of 4s. 10d. will be payable at 1, Cloth Hall-street, Huddersfield, on Sept. 23, to creditors of Harry Graham, electrician, &c., Albion-street, Huddersfield.

Digitized by Google

A dividend is to be paid to creditors of Harold Bristow, electrician, &c., 368, Hessle-road, Hull. Claims to Mr. G. H. Acheson, York City Bank-chambers, Hull, by Sept. 20.

The S.M.H. Tramway Synd. (Ltd.) is being wound up voluntarily. Mr. C. Whensa-Nicholl, 13, St. Helens-place, London, E.C., is liquidator.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

*NOTE.—The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked * are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. Names within parentheses are those of communicators of inventions. When complete Specification accompanies application, an asterisk is affixed.*

July 4, 1910.

15,929 NASMITH. (Tito Livio Carbone, Germany.) Enclosing the arc of arc lamps. (Addition to No. 17,448/09.)*
15,933 RUSSELL & HUTSON. Holders for electric incandescent lamps.*
15,938 HOSKINS. Rotary transformer.*
15,977 LEWIS. Electrodes for arc lamps. (Date applied for, 10/8/09, comprised in Application No. 18,649, dated 10/8/09.)

July 5, 1910.

15,988 RAILING & GARRARD. Electric cut-outs.
15,993 ELECTROMOTORS & GREENHALGH. Controlling the speed of electro motors.
15,996 THOMSON. Insulated metallic cable suspender.
16,017 SHAW & GREEN. Detachable power handle for controllers on electric cars, cranes and the like.
16,019 BRITISH INSULATED & HELSBY CABLES & REDFERN. Telephone exchange systems.
16,063 APOSTOLOFF & KARAVODINE. Manufacture of electrodes for secondary batteries or storage cells.

July 6, 1910.

16,093 HALL. Electric ignition apparatus for internal-explosion engines.
16,113 WILKES. Electric switching device.
16,152 MURRAY. Electrical switching mechanism.*
16,172 REEVE. Electrical apparatus.*

July , 1910.

16,211 TAYLOR. Limiting the flow of current on a short circuit.
16,253 CERREOTANI & SILBERMANN. Printing telegraph. (Date applied for, 7/7/09.)*†
16,256 16,259 & 16,260 LAKE. (Standard Chemical Co., U.S.) Production of resinous derivatives for insulating electric cables.
16,257 MERZ. Electric switches.
16,258 KALLMANN. Electric safety-fuses.*

July 8, 1910.

16,329 FRANCIS. Central energy electrical signalling system.*
16,330 & 16,334 GOLDSTEIN & POOL. Central energy electrical signalling system.*
16,331, 16332, 16333 & 16,336 GOLDSTEIN. Electrical signalling system.*
16,337 BRADY & HATRY. Electrical insulators.
16,342 SIEMENS & HALSKE AKT.-GES. Frequency meters for direct reading of or recording the frequency in alternating-current circuits. (Date applied for, 24/7/09.)*†
16,354, 16,356 & 16,364 EISENSTEIN. Producing electrical impulse charges for wireless telegraphy and telephony. (Addition to No. 10,019/08.)*
16,360 CERREOTANI. Wireless-operated electrical signalling indicating or like means. (Date applied for, 24/2/10.)*†
16,367 KELLER-DORIAN. Composite magnets.*

July 9, 1910.

16,404 HILL. Electric cut-outs or fuse switches.
16,419 KRAMER. Inductive wireless telephone installations.
16,424 MILCH. Alternating current dynamo-electric machines of the commutator type.
16,444 HEURTLEY. Telegraphy.
16,541 GRIMM. Electric glow lamps.

SPECIFICATIONS PUBLISHED.

1909 SPECIFICATIONS.

7,121 BERRY. Distribution of alternating electric current.
12,685 FIELD & FERRANTI. Generation, transmission and distribution of electricity.
14,833 HOLGRAVE-GRAHAM. Electric switches.
14,937 GRÜNWALD. Electrical induction furnaces. (Date applied for, 2/10/08. Addition to 3,599/09.)
15,167 PITTS. Telegraphy.
15,319 PÖHL & PHŒNIX DYNAMO MFG. CO. Dynamo-electric machines constructed with commutators.
15,325 LEITNER. Systems of train lighting.
15,494 CROMPTON & CO., MACFARLANE & BURGE. Motor-control systems and rotary electric transformers or motor-generators therefor.
15,647 LESSING. Manufacture of electric carbons.
15,899 LEITNER. Electric regulators.
15,896 KUTTNER. Insulation of electric conductor windings or coils made of aluminium or aluminium alloys.
16,076 PÖPE'S ELECTRIC LAMP CO. (Trenzen). Production of a metallic connection between incandescent filaments and their leading-in wires.
16,273 FEWTRELL. Electric switches.
17,254 HOFFER & GREENWOOD. Windings for the armatures of dynamo-electric machines and the like.
18,965 B.T.-H. Co. (G.E. Co., U.S.) Electrodes for arc lamps.
19,045 CONRADE. Wall sockets for electric couplings.
21,180 BARBOUR. Flexible electrical brushes or collectors.
22,087 MUNRO & RAILLESS ELECTRIC TRACTION CO. Trolley-arms or collectors for electrically-propelled vehicles running without rails.
22,454 ROYCE & HUTLEY. Electrical capstans, electrical cranes and other electrical hitting, winding or hauling appliances.
23,504 FREDERICKS, FREDERICKS, RUSSELL, WEDDING & CONNELLY. Trolleys for use on electric tramways on the overhead conductor system.
24,373 COLLINS. Electrical switches.
24,735 HARRIS. Electro-deposition apparatus.
25,577 WESTINGHOUSE. Conduits or castings.
28,532 REINISCH & KYNOCH. Electric fuses and detonators.
28,941 B.T.-H. Co. (G.E. Co., U.S.) Systems of electric motor control.
30,142 B.T.-H. Co., GRAY, ROGERS & HOLDEN. Electric meters. (Addition to 12,689/09)

1910 SPECIFICATIONS.

1,611 SIEMENS SCHUCKERTWERKE GES. Alternating-current polyphase commutator dynamo-electric machines. (Date applied for, 16/2/09.)
4,318 THOMSON. Electric circuit-closers.
5,261 ADAMS MFG. CO. (Cutler Hammer Mfg. Co.) Multiple switch devices for electric motors.
7,860 B.T.-H. Co. (G.E. Co., U.S.) Electric heating apparatus.
10,607 ALLGEMEINE ELEKTRICITÄTS GES. Control of electric motors. (Date applied for, 30/4/09.)
12,522 SCHULTZ. Electric switches. (Date applied for, 24/7/09.)

NEW COMPANIES, MORTGAGES AND CHARGES.

NEW COMPANIES.

ELECTRIC FIRE PREVENTION APPLIANCES & GENERAL MFG. CO. (LTD.) (111,671)—Reg. Sept. 9, capital £1,000 in £1 shares, to carry on the business of electricians, mechanical engineers, manufacturers and generators of electricity, manufacturers of and dealers in apparatus and appliances, &c. Private company.

ELECTRIC POWER PLANTS (LTD.) (111,672.)—Reg. Sept. 9, capital £15,000 in £1 shares, to carry on business of manufacturers of, dealers in and contractors for electric plants, turbines and apparatus, suppliers of electricity, &c., and to adopt an agreement with A. H. Gibbings and P. J. Mitchell. First directors, P. J. Mitchell, C. O. Bastian and A. H. Gibbings. Reg. office, Caxton House, Westminster.

FURNACES (LTD.) (111,612.)—Reg. Sept. 5, capital £12,000 in £1 shares, to carry on the business of furnace manufacturers, electrical and general engineers, founders, &c. Private company. First directors, J. P. O'Donnell and F. E. Jones. Reg. office, Palace-chambers, Westminster.

MORTGAGES AND CHARGES.

ELECTRICAL CONTRACTS & MAINTENANCE CO. (LTD.)—Issue on Aug. 4 of £200 debentures, part of a series of which particulars have already been filed.

CITY NOTES.

MEMORANDA (Sept. 15).—**Bank rate 3 per cent. (since June 9, 1910). Price of silver,** 24½d. per oz. Consols 80¼—80⅜ for money; 80⅜—80⅝ for **account. Consols** Pay Day, Oct. 5; **Stock and Shares Continuation Days,** Sept. 27 and Oct. 12; **Ticket Days,** Sept. 28 and Oct. 13; **Pay Days,** Sept. 29 and Oct. 14; **Mining Shares Carry Over Day,** Sept. 26.

PRICES OF METALS (London).—*Copper*, cash, 55⅛; three months, 55⅛. *Lead*, English, 12¾—13; foreign, 12⅝—12¾. *Spelter*, 23—23¼. *Tin*, English, 156—158; foreign cash, 158; three months, 157¼. *Iron*, Cleveland, cash, 49/3, three months, 50/1.

BROMLEY (KENT) ELECTRIC LIGHT & POWER CO. (LTD.)—The directors have declared a dividend at the rate of 4 per cent. (2s. per share), less tax, on the ordinary shares.

DIRECT SPANISH TELEGRAPH CO. (LTD.)—The directors have decided to pay, in addition to the dividend at the rate of 10 per cent. on the preference shares, an interim dividend at the rate of 4 per cent. (tax free) on the ordinary shares, both for the half-year ended June 30, payable on 1st prox.

MANILA ELECTRIC RAILROAD & LIGHTING CORPN.—A dividend of 1 per cent. has been declared for the quarter ending Sept. 30.

NEW SUPERHEATER CO. (LTD.)—At the statutory meeting on Tuesday the chairman (Sir C. E. Knox) gave particulars of the progress made. He said the Furness Railway Co. had four locomotives fitted with their system, and the company were more than satisfied with the working of the apparatus. The engines so fitted showed a remarkable gain in efficiency, and the coal saving effected was slightly over 18 per cent. The Furness Railway had recently decided to fit up four more locomotives. At present they were in negotiation with about a dozen railway companies English, Colonial and foreign. He looked forward with confidence to big developments in the future.

PUEBLA TRAMWAY, LIGHT & POWER CO.—The report for 1909 states that the results show a considerable improvement over those for 1908, the net profits in Mexico having been £48,677, against £27,354. The development of the Tuxpango Falls has not yet been commenced, but cannot be longer delayed. The growing demands of the City of Puebla, the absorption of the power at present available, and the terms of the company's concession from the city of Puebla make it essential that 15,000 H.P. should be available for sale within the city boundaries by 1913.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee have granted quotations to £3,150,000 4 per cent. preference stock and £3,791,106 4 per cent. debenture stock of the *London Electric Railway Co.* (in lieu of the securities of the Baker Street and Waterloo, the Charing Cross, Euston & Hampstead and the Great Northern, Piccadilly & Brompton Railways, and a further issue of £186,433 Metropolitan District guaranteed stock of the *Metropolitan Railway Co.* The committee have been asked to appoint a special settling day in, and grant a quotation to, a further issue of 62,500 $100 shares of the *Rio de Janeiro Tramway, Light & Power Co. (Ltd.)*

UNITED ELECTRIC CAR CO. (LTD.)—The directors' report for the year ended June 30 states that the works have been efficiently maintained out of revenue. After paying debenture interest (£2,475) and charging £5,586. 15s. 3d. for depreciation, the profit for the year is £8,478. 4s. 1d., to which is added £5,333. 9s. brought forward, making £13,811. 13s. 1d. After deducting the preference dividend for the six months ended Dec. 31, 1909 (£3,000) the available balance is £10,811. 13s. 1d. The directors recommend payment of the preference dividend (less tax) for the half-year ended June (£3,000) and a dividend of 2½ per cent. (less tax) on the ordinary shares for the year (£3,750), carrying forward £4,061. 13s. 1d.

NOTES.

Tariffs and Metal Filament Lamps.

THE announcement that the Metropolitan Electric Supply Co. have decided to raise the price of electrical energy, supplied on the flat rate, from 5½d. to 6d. will probably come as a surprise. The reason given for taking this step is that consumers making use of metal filament lamps require so much less energy than hitherto that it has become necessary for the price to be raised. We cannot help thinking that this is a retrograde step, more particularly as 5½d. cannot be considered a low price. As an alternative—and perhaps this step has been taken partly to force attention to the alternative—it is announced that a "telephone tariff," somewhat similar to that in force in St. Marylebone, is to be available to consumers. There is, however, rather an important difference between the proposed tariff and that in St. Marylebone, for in addition to the fixed annual charge payable in quarterly instalments a predetermined number of units, depending on the installation, is to be charged at 2d. per unit, and all additional units will then be charged at 1d. This complicates matters somewhat. It has the advantage, presumably, that the quarterly instalments are lower, and, consequently, the consumer will feel that he is not parting with too much money in advance. On the other hand the complication is a disadvantage. We incline to the view that if the telephone form of tariff is to be modified it would be much better to omit the fixed annual charge, and merely to charge a predetermined number of units per quarter at a higher price, such as 6d. per unit, all units in excess being charged at 1d. In any case the fixed annual charge depends upon the character of the installation, and therefore there is very little to support the criticism that the fixed number of units cannot be equally well so determined.

Science and Industry.

IN the concluding portion of his Paper on "The Relations of Science to Industry and Commerce," of which we give an abstract in our present issue, Mr. R. BLAIR makes a suggestion with the object of bringing technical colleges into closer touch with industrial works. The suggestion is that an Advisory Committee should be attached to all specialised faculties or departments, such committees to consist of industrial leaders or experts of the highest reputation. By so doing, the curriculum and examinations would be subjected to sympathetic criticism by experts of the first rank, and a medium of communication would be provided between the college and the workshop. Mention is made that on the Examining Committee of the Glasgow and West of Scotland Technical College are the engineering director of the Fairfield Shipbuilding & Engineering Co. and the engineering director of Messrs. John Brown & Co., who own the Clyde Bank Shipbuilding and Engineering Works. We think there is much to be said in favour of the suggestion, provided it is not carried too far and that it does not produce a committee which is unwieldy for the purpose.

FOR this method to be successful it would be essential that the right men should be upon the committee. If an attempt were made to obtain the services of what may be termed the engineering leaders in large manufacturing concerns, it is possible that such men would not be the most suitable for the purpose, because they might be out of touch with the students entering their works. The men whose opinions are really most desirable in this connection are those in contact with the students during their first few years in the works. For this reason it is just possible that a better result would be obtained if the teacher himself were enabled to get into touch with members of the staff occupying lower positions than the directors contemplated by Mr. BLAIR.

IN the discussion which followed the Paper it was noticeable that speakers were inclined towards the idea that our employers are not so bereft of science as some critics would have us believe, and that irritation is often created by the idea that the scientific man can merely, on account of his science, instruct the manufacturer as to how

Digitized by Google

his business should be run. This attitude of mind is not favourable to progress, and we are glad to see that it is breaking down. Among the suggestions made during the discussion, the remark of Sir WILLIAM WHITE, that post-graduate courses were often better taken in the works themselves, is worthy of notice. Sir WILLIAM also strongly advocated the multiplication of research laboratories in the works, and quoted, as a striking example of the success of this system, the research laboratories at Essen, in which Sir WILLIAM ROBERTS-AUSTEN'S classical researches on the treatment of steel were turned to very profitable account by Messrs. KRUPP. Obviously the research laboratory at a works, if properly equipped and properly run, has the important advantage over a college laboratory that it necessarily imbues the student with the importance of the commercial aspects of the results obtained, and therefore a turn of mind is developed which is not too academic.

Increasing Tramway Revenue.

ALTHOUGH the majority of tramways have hitherto been solely concerned in the conveyance of passengers, there does not appear to be any reason why a tramway should be confined to passenger traffic. This question was raised last Wednesday, at Bradford, by Mr. C. J. SPENCER, in his Presidential Address to the Municipal Tramways Association. As regards the delivery of parcels, considerable success has already attended experiments in this direction on a few undertakings. Amongst these, mention may be made of the Manchester Corporation tramways, which last year dealt with, on an average, over 16,000 parcels per week. In some cases, however, the proposal to undertake work of this nature has aroused considerable opposition; and an application to Parliament by the Bradford Corporation to grant further goods-carrying powers was recently unsuccessful, owing largely to the small use made of such powers in the past by other undertakings. It is, however, interesting to notice that large contracts for the carriage of material have been entered into by the Leeds Corporation Tramways. Other managers will, doubtless, watch with interest this experiment, as it may lead to greater financial success in the smaller class of tramway undertaking. The conveyance of mails for the Post Office authorities is another means of profitably utilising the tramway track. The whole question, in fact, requires the careful consideration of tramway committees, especially in those small towns where the traffic revenue per car-mile is low.

The Industrial Outlook.

IN another column we give a brief account of the proceedings at the Trade Union Congress, which was held at Sheffield last week. More than usual interest attached to its deliberations, as it was known that several questions of importance in the industrial and commercial world would be debated. One of the leading topics under consideration was the attitude of the boilermakers, who had thrown over their leaders and had refused to allow their executive to open negotiations with the masters. As is well known, this attitude, and especially the tendency of the boilermakers to indulge in sectional strikes, compelled the masters to give notice of a general "lock-out" unless the men gave an undertaking that they would abide by the terms of the agreement made some time ago between the representatives of both masters and men. The executive of the men's union appear to have been willing to give the required guarantee, but, when consulted, the men refused by a substantial majority to allow their executive to deal with the masters' representatives. Of course, the success of trade unionism is dependent upon what is termed the collective contract, but which we prefer to term collective bargaining It is obvious that if a bargain is only carried out by one of the parties so long as they derive full benefit from it, or so long as it is convenient to abide by the terms, the other will rightly refuse to negotiate in future. It is necessary to have discipline in large industrial establishments, and to have some certainty as to the future where large contracts are concerned. Therefore, it seems to us that the masters were justified in seeking a guarantee from the boilermakers that the men would refrain from starting sectional strikes without notice.

IT is greatly to be regretted that the present "lock-out" has entailed considerable suffering on many innocent persons who have no sympathy with the short-sighted policy of the men, and it is also to be regretted that the trouble should have arisen at this time when trade had begun to revive, when the shipyards were busy on home and foreign contracts, and when everything pointed to a period of prosperity which is much needed after the recent depressed condition of business in this country. It is not alone in the shipbuilding industry that there is evidence of industrial unrest. The cotton and the mining industries are also affected, but it is to be hoped that the leaders will be able to infuse a spirit of discipline into the ranks of the men, and that masters and men will be able to settle their differences by arbitration or some such peaceable means. The strike and the "lock-out" are economically indefensible, and, moreover, they are barbarous methods of settling differences. We should like to see the principle of arbitration extended to all disputes between masters and men. It would be better for both sides, and it would be better for the trade and industry of the country.

Antennæ of German Military Wireless Stations.—According to the "Elektrotechnische Zeitschrift" the 300 ft. masts which carry the antennæ of the military wireless stations at Göttingen, Metz and Strassburg are giving every satisfaction, in spite of the violent storms and the large amount of ice and snow that has clung to them during the year. These masts are of wood, the accessories by which they are assembled being of cast iron, while the tension cables, which are fitted with bell insulators every 30 ft., are of steel. The larch beams are so arranged that the finished mast represents a truncated pyramid of rectangular section with 2 ft. 8 in. sides at the bottom and 12 in. sides at the top. The beams are prepared for use and impregnated with carbolineum at Berlin, so that at the place where they are to be used only assembling is necessary. The masts are carried on concrete blocks of square section 4 ft. 6 in. high. The cost of a mast, including all accessory expenses, is about £400.

Metal Filament Lamps for Street Lighting in Chicago.—According to the "Electrical Review and Western Electrician" the installation of special tungsten clusters along the outlying business streets of Chicago is progressing steadily. There has just been completed the installation of 51 posts on West Chicago-avenue between Ashland and Western-avenues, and 50 posts on East Thirty-first-street between Michigan and South Park-avenues. These posts carry four tungsten lamps each and are installed, lighted and maintained by the Commonwealth Edison Co. Over 1,000 of these posts have now been placed along the Chicago streets in front of the premises of such merchants as have agreed to pay the low rental charge.

Hydro-Electric Plant on the Hudson River.—The "Electrical Review and Western Electrician" states that a hydro-electric power house is to be erected on the west side of Green Island on the Hudson river, the capacity of which will be about 6,000 H.P. This power will be available not only for the present industries on the Troy side of the Hudson River, but will also offer exceptional advantages to other industries both in Troy and Green Island, which at present use purely hydraulic power. The amount of electrical energy thus generated will, in fact, be equivalent to a three-fold increase compared with the present hydraulic supply. Electrical energy will be sold to consumers by the Government (who own the plant) at the cost of production, or about a third of the cost of the power generated at Niagara Falls. It is mentioned, however, that it will be necessary for the companies using the power to meet the cost of constructing the power house.

Electricity Supply in Paris.—In a recent issue of "L'Industrie Electrique" is given a short account of two new generating stations which are to be constructed, one in the north and the other in the south of Paris, in connection with the new combined scheme which was formulated some time ago. The construction of these stations, which will be built at Saint Ouen and Issy-les-Moulineaux, will shortly be begun. The generator sets will each consist of a steam turbine, with surface condenser, direct coupled to a two-phase alternator supplying current at 12,300 volts, and a frequency of 41·66. The output of these sets will be 10,000 kw. There will also be two continuous-current generators mounted on the same shaft as the alternator, the purpose of these generators being to supply energy to the condenser motors, and for excitation purposes respectively. Each turbo-generator will be capable of taking a load of 12,500 kw. for two hours after having run fully loaded, and a load of 15,000 kw. for half an hour directly after the smaller overload.

An Electrically Driven Rolling Mill.—According to the "Revista Tecnica d'Elettricità" the Terni steel works have just decided to erect a mill for rolling armour plates to take ingots weighing up to 100 tons. It will consist of a double reversible train, 5 ft. in diameter and 15 ft. wide. The steel works in question are at present employing water power, but as turbines are not reversible electrical driving had perforce to be used. The rolling train is driven by two continuous current motors which are coupled together and develop a horse-power of 15,000 when running at 90 revs. per min. These motors are fed from three dynamos working in series and directly connected to a hydraulic turbine of 2,600 H.P. capacity. In order to equalise the peaks in the demand this set is fitted with a flywheel weighing 70 tons. The turbine runs at a speed of from 360 to 450 revs. per min. The prompt way in which the mill can be reversed by the use of the electric drive is the special feature of this new installation. Very rapid rolling can be obtained, while excessive wear on the rolls and uneveness in the work due to sudden stopping can be avoided.

Re-opening of the British Section at the Brussels Exhibition.—The new British section of the Brussels Exhibition which has just been built to replace the buildings destroyed by the fire of August 14th were opened on Tuesday last by the King of the Belgians. It will be remembered that the Board of Trade and the British Commission were unanimous in deciding to restore the British section as far as possible to its former excellence. The response to the appeal for fresh exhibits was so spontaneous that only a portion of those anxious to be represented could be accommodated with space. The new section now fills the Salle des Fêtes, a much smaller space than was originally occupied, but still sufficient to admit an admirable selection of British exhibits. We understand that the most stringent regulations have now been enforced to prevent any further outbreak of fire. One of the few firms whose exhibits came to no injury was the Thermal Syndicate, who were showing crucibles and other silica apparatus. This firm were thus provided with an entirely unsolicited testimonial to the worth of their goods.

Casualties on American Electric Railways.—According to the "Electrical Review and Western Electrician," the report of the Interstate Commerce Commission relative to railway accidents for the first three months of the present calendar year shows a material increase in the number of persons killed and injured. During the first three months of 1910 the number of persons killed on electric railways throughout the United States was 19, and the number of injured 669. This is but a very small fraction of the loss of life and injury reported for the steam railways of the country for the same three months. For the steam lines the number of persons injured during January, February and March of the current year was 21,232, as against 6,110 in the corresponding three months of 1909, and the number of persons killed, 1,100, as against 466 in the same period of 1909. These figures deal only with employés on duty and passengers, and take no cognisance of trespassers. Attention is especially called to the fact that the number of casualties for the quarter above referred to were materially swelled by two great disasters, the avalanche in the State of Washington and a derailment in Iowa.

Mains Extensions in Northumberland and Durham.—In the counties of Northumberland and Durham some very important extensions of the network of the Newcastle-on-Tyne Electric Supply Co. and the County of Durham Electric Power Companies have recently been carried out. Some particulars of these may be of interest. Upon the route from Holywell to Seghill a 12,000-volt feeder has recently been erected in order to duplicate the existing supply. The normal span between poles on this feeder is 80 yds., each pole carrying three conductors, each of 0·05 sq. in., the conductors being of copper. For roads and railways catenary guarding has been adopted, while lace guarding is used for footpaths. The feeders commence by a junction with the underground cable near the Holywell Colliery, and a three-cored lead-covered pilot cable is also carried along the route. The work has been done by the British Insulated & Helsby Cables Ltd. The same Company has also erected a pole line from the Rising Sun pit to Backworth in the County of Northumberland, in connection with the same mains system. The Newcastle-on-Tyne Electric Supply Co. has also ordered a new 12,000-volt feeder to run from the Newsham switchhouse to Seaton Delaval, a distance of 3½ miles. The line is of the same dimensions as the one mentioned above, and also carries lead-covered pilot and telephone cables slung from the catenaries. Another important extension which is in prospect and has just been placed on order, is a new 20,000-volt pole line from Carville power station to Burradon. This line is a three-phase supply with 0·1 sq. in. copper conductors, a pole line joining the underground cable at a point just outside Wallsend. The purpose of this pole line is to duplicate the existing supply.

Music by Wireless.—A recent issue of the "Electrical World" states that the method of reproducing by magnetic induction musical and vocal sounds in a pair of telephone receivers connected to a coil of wire held in the hands of the auditor, which was first publicly demonstrated at the Louisiana Purchase Exposition at St. Louis in 1904, is being revived as an amusement feature among a number of summer parks of the country. Entering the enclosure or building in which the "wireless" is installed, the visitor is handed a basket containing a coil of wire, to which a head-receiver is connected.

Digitized by Google

On placing the receivers to his ears he hears accurately the telephoned phonographic selections of his favourite band or opera singer. The method employed in these amusement devices is to string round the outside of the room or building from 80 to 100 turns of wire, the ends of which are led out to a telephone transmitter in series with a strong battery of dry cells. A phonograph horn is directed into the telephone transmitter, and currents corresponding to the sound waves are set up in the large coil, which in turn induces a varying magnetic field throughout the building. The small hand-loops connected to the telephone receivers then act as the secondaries of the air-core transformer or repeating coil thus produced. The phonograph attachment and transmitter may be located in a building at some distance from the wireless pavilion.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. K. M. Faye-Hansen contributes an article on "Voltage Drop of Transformers having a Poor Regulation."

At the Conference of the Municipal Tramways Association, held at Bradford this week, the presidential address was delivered by Mr. C. J. Spencer. An account of the proceedings, together with an abstract of a Paper on "The First Decade of Municipal Tramway Working," by Alderman S. Flint, are given in another column.

We conclude our abstract of the Paper on "The Relations of Science to Industry and Commerce," read by Mr. R. Blair at the recent meeting of the British Association. An interesting discussion, of which we give an abstract, took place.

We give an account of recent developments in the use of metal filament lamps for street lighting and other purposes. Several central station engineers have supplied us with particulars of the progress made in their districts, whilst some interesting information has also been obtained as to the use of metal lamps by the railway companies.

The important subject of the electrification of the Melbourne suburban railways was advanced a stage by a declaration in the Victoria Legislative Assembly by Mr. Murray, the Premier, to the effect that there was no question now as to the electrification of these railways. That must come. The Railway Commission that was appointed to consider the general question of electrification was not to enquire into this particular matter, as sufficient information was available in Mr. Merz's report. (See THE ELECTRICIAN for Sept. 18 and 25 and Oct. 2, 1908).

The Institute of Metals has reached a membership of 1,000, and has now been registered without the word "limited" by licence from the Board of Trade.

A proposal put before Weymouth Council by the Electric Lighting Committee to obtain powers for the construction of tramways in the borough, at an estimated cost of £27,000, has been withdrawn. Another scheme is to be prepared.

We give in another column an abstract of an interesting report by the British Commercial Attaché at Peking.

It is announced that Mr. J. E. Kingsbury has joined the board of the Western Electric Co.

An Indian company has been formed with a capital of £1,250,000 to carry out the Bombay hydro-electric scheme.

Ganz & Co. have secured the concession for the erection of electricity and gas works at Constantinople.

Keighley Council have decided to promote a bill to authorise the running of railless trolley cars.

Loans for Electricity Supply.—Manchester Corporation have applied for sanction to a loan of £30,000 for additional generating plant for Stuart-street station.

Norwich Council have applied for sanction to a loan of £18,790 for extensions of the electricity works.

Arbitration.—The arbitration proceedings between the Torquay Tramways Co. and Torquay Corporation to decide whether the latter have unreasonably withheld their consent to the reconstruction of certain surface-contact tramways on the overhead system, were concluded on Saturday. The arbitrator (Mr. Archibald Read) reserved his award.

Directors' Reports, &c.—The report of the directors of the British Thomson-Houston Co. states that extensions and improvements of the main factory and the incandescent lamp factory have been made, and the company has exchanged licences with the Osram Lamp Works (Ltd.) of all its metal filament lamp patents.

The Allgemeine Elektricitäts Gesellschaft, Berlin, have declared a dividend of 14 per cent. for the year 1909-10, compared with 13 per cent. for the previous year. Orders in hand show a considerable increase over those of the previous year.

At the meeting of the Underground Electric Railways Co. of London on Wednesday Sir Edgar Speyer stated that the tube railways continued to make steady progress, and there was a considerable decrease in expenses, due to the reduction of price of electric current.

INSTITUTIONS AND SOCIETIES.

Association of Mining Electrical Engineers.—In connection with the efforts which have recently been made to form in Scotland two branches of this Association—one for the East and the other for the West of Scotland—a representative meeting of those engaged in the application of electricity to mining was held in the Grosvenor Restaurant, Glasgow, on Saturday evening last. Mr. H. W. Clothier (Newcastle-on-Tyne) presided, and was supported by Mr. J. Glynn Williams (Whitehaven), both gentlemen being present as a deputation from the General Council of the Association. After the chairman had explained the objects of the Association Mr. J. Glynn Williams read a communication from the President of the Association, Mr. Wm. Maurice, in which the latter mentioned that every miner who was studying to qualify for the position of a mines inspector or colliery official would find it greatly to his advantage to join, and every acting colliery official ought to take advantage of the opportunity which the Association offered, even if he did so only on the ground of self-preservation. The following officials were then elected by the members of the West of Scotland branch present:—*Chairman*, Mr. Alexander Anderson (Motherwell). *Vice-President*, Mr. Matthew Brown (Dennyloanhead). *Secretary*, Mr. D. Martin (Glasgow). *Treasurer*, Mr. D. Landale Frew (Glasgow). *Members of Council*, Messrs. J. Thomson (Hamilton), W. Cairns (Glasgow), J. R. Benson (Dennyloanhead), C. W. Holman (Glasgow), F. Anslow (Glasgow), H. A. McGuffie (Glasgow), D. M. Mowat (Coatbridge), R. Edwards (Glasgow), J. C. McCallum (Kilmarnock), W. A. Wilson (Glasgow), R. Robertson (Stonehouse) and A. Power (Uddingston). In intimating that as the outcome of the meeting the membership of the Glasgow branch had been increased to upwards of 50, Mr. Williams called attention to the meeting which it was proposed to hold in Dunfermline on the 24th inst., with a view to forming a further branch in the east of Scotland.

The Tramways and Light Railways Association.—The "Official Circular" of this Association for September contains several matters relating to the work of the Association, an article on "Car Meters," and full translations of two reports submitted at the recent International Tramway Congress in Brussels on the same subject, giving the results obtained all over the Continent from the use of these instruments on tramcars; a table is also given showing the financial results achieved in concise form.

Manchester Section of the Institution of Electrical Engineers.—The committee of this section of the Institution of Electrical Engineers has decided to open the coming session with a conversazione, as it is felt that this will be the most convenient way for the incoming chairman to meet the members of the local section, while it will also afford a suitable opportunity for members and friends to meet and discuss matters of interest. The conversazione will be held on Friday, October 14th, at the Manchester Whitworth Institute, Whitworth Park, Manchester, commencing at 7:30 p.m. After the reception by the chairman there will be instrumental and vocal music, and refreshments will be provided. Applications for tickets should be made to the honorary secretary, Mr. H. W. Wilson, or to members of the committee.

ARRANGEMENTS FOR THE WEEK.

FRIDAY, September 23rd (to-day).

MUNICIPAL TRAMWAYS ASSOCIATION.

10 a.m. Annual General Meeting in the Town Hall, Bradford.

SATURDAY, September 24th.

ASSOCIATION OF ENGINEERS-IN-CHARGE.

5:15 p.m. Reception at the Engineering Exhibition, Olympia. Lecture at 7:45 p.m. on "Wireless Telegraphy, its Maritime Importance," by G. Langler Bullocke.

IRON AND STEEL INSTITUTE.

Autumn Meeting at Buxton (Monday, September 26th to Friday, September 30th). Among the Papers to be read are: 'On Electric Steel Refining," by Mr. D. F. Campbell; and "The Utilisation of Electric Power in the Iron and Steel Industry," by Mr. J. J. E. Schuurman.

THE USE OF METAL FILAMENT LAMPS FOR STREET LIGHTING AND IN RAILWAY WORKING.

In former years it has been our custom to enquire of supply engineers as to the results they have obtained from the use of metal filament lamps in their districts, when employed both for street lighting and other purposes. The results of these enquiries have been satisfactory; metal filament lamps, we have been told, are eminently suited for this purpose and afford a very efficient means of illuminating streets and districts where high-power flame arc lamps would be out of place.

This year we have again made enquiry of a number of engineers who are employing this type of lamp for street lighting purposes and the answers are again satisfactory, from the electrical point of view. A pleasing absence of detail is to be noticed. Many of our correspondents inform us that there is little to add to what they said last year, nothing sensational having happened, but, on the other hand, the employment of the metal filament lamp for street lighting is steadily increasing and both by its long life and efficiency this type of illuminant is proving itself eminently suitable for the purpose.

Street Lighting.

Turning to the actual replies we have received, one well-known engineer, who is for ever waging war against the claims of the gas companies, informs us that by the use of metal filament lamps, instead of gas, a saving in running costs of £1,500 per annum has been effected, while the candle-power has at the same time been improved, and that his council have decided to spend £20,000 in converting the whole of the gas lamps in the borough for electric lighting. Great care has been taken so to arrange the lamps and reflectors that an even distribution of light between the posts is obtained, and the bright spot at the foot of the post, which is so often found in the case of gas, is thereby altogether avoided.

Mr. A. C. Cramb, of Croydon, informs us that since the end of September, 1909, the number of metal filament lamps used for side street lighting in that borough has been increased from 265 to 330, while special street lighting mains have been also laid in certain streets, and that here some gas lamps are being replaced. For side-street lighting the unit is one 200-volt 77-watt lamp, which is fixed in a fitting with a specially designed reflector. These lamps have given very satisfactory results, an average life of nearly 3,000 hours being obtained.

As showing the way in which metal filament lamps have replaced arc lamps, Mr. Cramb informs us that during the past year he has scrapped 255 450-watt and 650-watt alternating enclosed arc lamps. These have been replaced by lanterns having a large vitreous enamelled reflector and containing three 100-watt metal filament lamps. As approximately half of these are fixed on the tramway poles, the lampholders are provided with an anti-vibration holder. The average life obtained from these lamps so far is approximately 2,200 hours, but it is anticipated that this will be increased at the end of the year as many of the lamps are still running. The main London to Brighton road, on the other hand, has flame arc lamps installed throughout the greater part of its length, and the remainder is illuminated by Osram lamps. The centre part of the town is about to be changed to flame arc lamps.

Mr. Geo. Wilkinson, of Harrogate, sends us some very interesting information. He informs us that the cost of gas from the gas company to the Corporation, including everything except labour, cleaning and lighting, is 17s. per lamp per annum, and the lamps are extinguished about 12:30 a.m. The electricity department have, nevertheless, received instructions to change 500 gas lamps to electricity. They will be able to provide a better light, furnished by means of metal filament lamps, at an actual cost to the Corporation of 11s. 2½d., including lamp renewals and everything except cleaning and lighting, or a reduction on the former price of 33⅓ per cent. There will be some saving also in the cleaning, as electric light does not coat the glass with a smoky film as does gas; furthermore, in most of the lanterns there will be no glazing, excepting in the nature of a reflector over the lamp itself. The Corporation are paying the electricity department 17s. per annum, the same price as to the gas company excepting that the 17s. per post for electric lighting includes lamp renewals, and the difference in the actual cost and the amount received will pay for the cost of the conversion in a very few years. The 500 new electric lamps referred to are to be located in positions where there are already low-pressure electric mains, and the estimated cost of fitting the existing gas lamps complete is £800.

With regard to photometric tests, Mr. Wilkinson has made some interesting investigations in the streets of Harrogate. Two separate tests were taken on the metal filament lamps and on an "alleged" 60 c.p. gas mantle. These were taken at random in the street with the following results: The metal filament lamp gave actually 54·5 c.p., while the gas mantle actually gave only 25·3 c.p. A month later the metal filament lamp gave 54·6 c.p., while candle power of the gas mantle had increased to 36·1 c.p. The gas mantle had, Mr. Wilkinson remarks, evidently been changed during the interval. These tests were made on posts and lanterns of exactly the same type, one carrying the latest form of gas mantle and the other a tungsten filament lamp. It will be seen, therefore, that, as Mr. Wilkinson points out, the electric lamp gives a very much better illumination than does the gas mantle. The photometric tests were taken with a Haydn Harrison portable photometer. The tests were all taken at one angle, and the posts were of the same height.

Mr. Christie, of Brighton, informs us that he now has got 1,834 old gas lamps converted and connected to the network in such side streets which are not of sufficient importance to justify arc lighting. When electricity was first employed for this purpose, the lighting consisted of two 8 c.p., two 16 c.p., or two 32 c.p. carbon filament lamps. When metal filament lamps first came in, where these posts were situated in the 230-volt area, the holders were arranged to take two of these lamps working at a pressure of 115 volts in series. During the past year, however, the whole of these posts have been altered to a single point on the 230-volt system, so that high voltage metal filament lamps in units of 32, 50, or 100 c.p. can be employed.

Mr. Christie's experience with the leading makes of these lamps is that they are steadily improving, both as regards efficiency and life, and in many cases individual lamps are actually burning for upwards of 5,000 hours without any apparent diminution in the candle power. The average life of the best makes of these lamps, however, is, he considers, not so good as it might be, and he thinks the high efficiency of a little over 1 watt per candle-power might be sacrificed to a small extent with advantage both to the lamp making industry and to the user if a longer life could be assured.

The economies which the consumer has been able to effect in his electricity bill by their use have been so great that it does not appear that he would grudge paying the supply undertaking a little more if he could prolong the life of his lamps, and thus reduce the cost of renewals. Mr. Christie considers few users would object to 1½ watts per candle-power as a standard, and the extra 0·3 or 0·4 watts would give the makers a wider margin to work on, which, in time, should tend to reduce the cost of manufacture.

Mr. H. D. Munro, of Exeter, informs us that he has now some 500 metal filament lamps in Exeter in use for street lighting. These have been working for some three years, as Exeter was among the first stations in the country to adopt them. The supply being at 100 volts, no trouble whatever has been found from vibration effects, although 100 c.p. lamps are attached to the tramway poles, and no special anti-vibration fittings have had to be used. An average life of more than 2,500 hours is obtained for the whole of these lamps, and experience goes to show that a better average light than is obtainable from low-pressure gas mantles can be given by electric metal filament lamps at a cheaper rate without unduly cutting the price of the supply. The introduction of this large amount of street lighting, Mr. Munro continues, has undoubtedly improved the estimation in which electricity

Digitized by Google

is held by the public, and private consumers have noticeably increased in consequence. The general adoption of metal filament lamps has, of course, cut into the revenue, and will continue to do so as the smaller size lamps are taken up, but he finds that the increasing popularity of the light has practically made up the loss occasioned by the great economy of the metal lamps.

Mr. C. A. L. PRUSMANN, of Swansea, informs us that during the past 12 months he has every reason to believe, both from an illumination and financial point of view, his Council have been very well satisfied with street lighting carried out by means of metal filament lamps. He further adds that he has received instructions to replace existing gas lighting by means of metal filament lamps in those streets where distributing cables are already laid.

A large amount of gas lighting has been replaced during the past 12 months in the main thoroughfares by means of arc lighting, and he anticipates a considerable increase in the near future in electric street lighting both by means of arc and metal filament lamps. He is strongly of opinion that the introduction of metal filament lamps has had a beneficial effect on the general working of the station. At the present moment there appears to be no reason why this effect should not continue in the future.

Mr. A. DIMMACK, of Swindon, gives us the following information regarding the metal filament lamps at use in Swindon. Since March, 1908, the following is a record of lamps that have failed :—

Between	0	and	110	hours	27	lamps
,,	100	,,	200	,, ...	23	,,
,,	200	,,	500	,, ...	61	,,
,,	500	,,	1,000	,, ...	59	,,
,,	1,000	,,	2,000	,, ...	76	,,
,,	2,000	,,	3,000	,, ...	62	,,
,,	3,000	,,	5,000	,, ...	45	,,

There are a number of lamps which have burnt over 5,000 hours and are still burning. The average life of the lamps has been 1,534 hours.

Mr. H. CAMERON, of Penarth, informs us that since last October he has increased the number of metal filament lamps that he is using for street lighting to a small extent. The life of these lamps is still satisfactory, and he has at present at work three lamps which have already been burning over 6,000 hours. The average life, however, appears to be between 1,500 and 2,000 hours. Very few carbon lamps are now being supplied by his Company, their place having been almost wholly taken by 55-watt metal filament lamps.

OPINIONS FROM RAILWAY ENGINEERS.

Next to electricity supply authorities it may be said that those most intimately connected with the use of metal filament lamps for all purposes are the railway companies. Such concerns have a great variety of places to light—offices, stations, goods yards, running sheds and even the trains themselves, so that the experience railway electrical engineers have obtained with metal filament lamps should be of very great value. Such experience is, however, of slow growth, and although many railway engineers have informed us that they have replaced carbon by metal filament lamps practically all over their systems and that the new lamps seem to do their work very well, yet it is too early for them to give us the information we require in any great detail.

The CALEDONIAN RAILWAY are using these lamps for the lighting of railway stations, goods yards, shops and running sheds; the LANCASHIRE & YORKSHIRE RAILWAY are using them for the lighting of the first-class carriages on their system, and also largely for general lighting instead of arc lamps. In fact, it would seem, we are informed, that these lamps will supplant the arc lamp very largely, if not entirely, in railway working. The SOUTH EASTERN & CHATHAM RAILWAY are also using this type of lamp extensively for the lighting of station platforms, and offices, goods yards and houses.

Again, Mr. VINCENT L. RAVEN, chief mechanical engineer of the North-Eastern Railway, informs us that metal filament lamps are largely being used on that system in connection with ordinary office lighting, suburban station platform and siding lighting, hotel lighting, loco., carriage and wagon works lighting and signal cabin lighting. The platforms of large stations where electricity is used are lighted by arc lamps, as are the goods yards and running sheds. The North-Eastern Railway have not found metal filament lamps suitable for such places for general illumination. Their experience of metal filament lamps, for the places where they are in use, is, however, now very favourable since improvements in the life of filaments have been made, and the lamps have been available for the higher pressures without alterations to the wiring. The advent of the low candle power, high-pressure lamp, has, Mr. Raven considers, also considerably increased the utility of the metal filament lamp. The saving in consumption is very considerable, and even with the high prices now obtaining, the use of metal filament lamps is more economical than the carbon filament lamp at about one-fifth the price of the metal filament lamp. The economy, of course, is greatest at the places where the price of energy is high.

Mr. H. W. FIRTH, Electrical Engineer of the Great Eastern Railway, tells us that this Company have several thousand tungsten and tantalum lamps in service under various conditions, as regards vibration and rough usage. The results obtained as far as the actual average life of lamp is concerned have been highly satisfactory, the burning life usually amounting to some 1,500 hours. Considerable use has been made of 100 c.p. and 200 c.p. tungsten lamps for the displacement of high power incandescent gas in goods and shunting yards. As a rule there has been no need to fit these lamps with spring suspensions, but this precaution has been taken in places where pronounced vibration obtains. Enclosed and open type arc lamps are also being displaced with satisfactory results from the economical point of view by metal lamps in positions where head room is limited—for instance under station awnings and so forth—and where the distribution of light can be much improved by increasing the number of units. At busy goods yards where carboning of lamps is difficult and expensive owing to the heavy van traffic in the roadways, considerable economy can be effected over arc lighting (if conditions as regards distribution of light, &c., are not unfavourable) by the installation of metal lamps. Tungsten lamps in small units are successfully employed at certain stations, advantage being taken of the alternating system of distribution to step down the lamp voltage to 55 volts. At country stations beyond the reach of a distribution system supplied from a central source, the low-voltage wire lamp is being used in conjunction with paraffin electric generating sets and batteries. The first plant of this kind on the Company's system will be running shortly, and it is anticipated that this method will prove more economical for isolated stations than any other system of illumination, while the capital cost will be quite moderate when it is remembered that even at small country stations the lighting load factor is comparatively high.

On the TUBE RAILWAYS, too, metal filament lamps are being extensively used, and in this connection we may deal with the experience of Mr. E. P. Grove, of the Central London Railway. Mr. Grove points out that in considering the use of metal filament lamps, probably the point which most concerns engineers of railway companies generating their own electricity is the price at which they are to estimate the current used for lighting purposes. In the case of the Central London Railway about 16 per cent. of the output from the power house is for lighting purposes, and were this to be reduced by 50 per cent. by the use of metal filament lamps the load factor would not be improved, while the load would become more variable by reducing the steadiest portion of it. This, therefore, would not tend towards economy in the power house, while, in the case of the Central London, at any rate, capital charges have not to be taken into consideration, as these are now practically fixed whatever the output. Really, then, the only saving made by reducing the current consumption would be in coal, and possibly very slightly in oil and water and small stores. Sub-station charges would not be reduced by the change, but the cost per unit would rather be increased; thus no allowance is made for sub-station charges, so that ,

Digitized by Google

when arriving at the total cost of lighting by the two systems, carbon and metal filament lamps, the coal cost only is considered. In the case of the Central London this would be about 0·215d. per unit delivered at the lamp terminals.

With the present price of metal filament lamps and a 5 per cent. increase on this price, due to requiring the lamps for series burning, the saving is questionable, as from experience obtained so far on the Central London Railway the life of the metal filament lamp is considerably below that of the carbon filament lamp using, say, about 4 to 4·5 watts per candle.

Recently the lamp bill on the Central London was considerably reduced by specifying lamps of medium, if not low, efficiency, and this without increasing the cost of lighting.

In the case of the Central London the lighting nearly all consists of either five 110-volt, four 135-volt or two 275-volt lamps in series, on a 550-volt continuous-current system, and the standby lighting is supplied from batteries. To alter this to a lower voltage continuous-current system would, of course, be out of the question. To alter it to an alternating-current low-tension system with transformers at the sub-stations would mean some other provision for a standby.

Suitable terms from a public electric supply company could hardly be obtained for merely standby energy in the case of momentary failure, with the prospect of having to take on 300 kw. or 400 kw. of lighting load at any moment without warning, possibly at the time of their peak, besides the fact that an alternating-current standby is not feasible at all points of the Central London system.

An alternative to this is a standby in the form of a few lamps supplied by a public supply company and kept always in use, for which, no doubt, reasonable terms could be arranged.

The question then arises as to whether this is as satisfactory as the present battery standby, which is capable of taking care of the whole of the lighting, including the arcs. Except for this feature, with 100-volt metal filament lamps, possibly even at the lower candle-power, Mr. Grove thinks it quite likely that these would show an all-round economy, provided the lamps did not have to be run in series, and he is about to make some tests in this direction.

As far as regulation of voltage is concerned, Mr. Grove does not think that has much effect in this case, as he is sure the regulation on the Central London is better than on many of the public electricity supply companies' mains, judging from the reports which have reached him from friends who have given up metal lamps on account of the enormous variation which they have experienced in the voltage of their supply mains.

With regard to the lighting of trains, some tests have been made in this direction, but these are not completed. As far as they have gone they have been in favour of the carbon filament lamps on account of the much longer life. These tests are being made with 110-volt lamps run five in series.

Tests are also being made as regards the use of the new lamp for sign lighting where the metal filament lamp has an advantage quite irrespective of its economy in current consumption, due to the fact that it dissipates so much less heat, than do carbon filament lamps when boxed up, which have a comparatively short life.

As compared with arc lighting, Mr. Grove considers there does appear to be some economy by the use of high candle-power metal filament lamps with suitable shades, due not to the fact that there is a reduction in the current per candle-power but to the fact that it is possible to use less total candle-power with metal filament lamps on account of the better distribution as compared with arc lighting. It is very questionable, however, whether the general appearance is as cheerful or as satisfactory from the public point of view.

As regards the DISTRICT & LONDON ELECTRIC RAILWAYS, Mr. A. R. Cooper, engineer, informs us that the arc lamps are being replaced at the lower stations of the tube, and the majority of the arc lamps at top stations, by metal filament lamps of 100 c.p. in connection with the replacement of carbon by metal lamps. Further the Eastern Joint and Whitechapel and Bow stations, as well as several stations on the District Railway, have also been lighted with metal filament lamps. The question of voltage supply is, Mr. Cooper thinks, one of importance, and it has been decided to adopt that of 60 volts throughout the system, except at the general offices, where, in view of the more delicate handling and the absence of vibration, a 100-volt circuit has been arranged for. A feature of the installation—particularly so far as the large units are concerned—has been the obtaining of reflected light, or more correctly the keeping out of direct vision of the lamps themselves, by large shades, frosting of the bottom portion of the lamp bulb, and other means. Mr. Cooper states that the saving in current consumption, especially so far as the arc lamps are concerned, has been considerable. On test many lamps show a life of 5,000 hours.

There is much to be said, Mr. Cooper thinks, for arc lighting in yards or at stations where they can be placed at a sufficient height to get an equal diffusion of light. On the tube railways, however, the arc lamps could only be fixed 11 ft. above the platforms.

Mr. R. P. Brousson, of the GREAT NORTHERN & CITY RAILWAY, informs us that metal filament lamps have been used on the Great Northern & City Railway for train and station lighting for the past two years with very good results, both from the financial and illuminating points of view. The lamps used for train lighting have an efficiency of 1·7 watts per candle, and an average life of 2,000 hours has been obtained, which compares favourably with the 800 hours of useful life obtained from carbon filament lamps. The lamps used for station lighting have an efficiency of 2·2 watts per candle, and the average life is from 4,000 to 5,000 hours as compared with 1,000 to 1,200 hours of the carbon lamp previously used; a considerable number of lamps (about 10 per cent.) have given a life of from 8,000 to 10,000 hours.

The above lamps are run five in series on a 550-volt traction circuit, but in all cases lamps rated for a pressure 10 per cent. above that of the declared pressure have been used, *i.e.*, five 120-volt lamps are used on a 550-volt circuit, as this can be done without materially affecting the illuminating power of the lamp. Undoubtedly, he thinks, the long burning hours are largely due to this precaution.

From the point of view of illumination, Mr. Brousson finds the metal filament lamp is unquestionably an improvement on the carbon lamp due to its whiter light; moreover the fluctuations in pressure, which exist on a traction circuit, are not so perceptible with metal filament lamps. In addition to tantalum lamps, several small experiments have also been made with tungsten filament lamps, but not with satisfactory results. The longest life that was obtained from these tests was 400 hours. This result is no doubt due to the filaments not being mechanically strong enough to withstand the vibration which exists on an underground railway. At the present moment a more extensive trial of tungsten lamps is being made. The platform arc lighting (5-ampere enclosed continuous-current lamps) at one of the underground stations has been recently replaced by high candle-power drawn tungsten metal filament lamps. Each arc lamp has been replaced by two 100 c.p. metal filament lamps. The better light distribution has led to a distinct improvement in the general illumination of the station.

Mr. Brousson has noticed an interesting point in connection with the train lighting, viz., in cold weather the metal filament lamps are more liable to fail than at normal temperatures.

From the above opinions on the working of the metal filament lamps, taken from the experience of those who have them operating under a number of varying conditions, it would seem that the initial stage in its development has now been passed. Though its average life is not perhaps so long as that of the carbon lamp, yet individual members of the tribe hold out well. There is no doubt about its efficiency, and the only thing that seems to be required is that it should be a little cheaper. This will doubtless come in time. Meanwhile we may congratulate ourselves on the fact that far from the metal filament lamp causing the disruption of the electrical industry, it has enabled the industry to extend its borders.

SOME NOTES FROM MAKERS OF METAL FILAMENT LAMPS.

In the following article we give some of the experiences of metal filament lamp makers during the year. They are rather meagre, for it is evident that the makers have very little to tell us, except that they are making and selling the lamps at a great rate. This is satisfactory as far as it goes, but does not provide us with very much to say on the subject.

The Osram Lamp.

The General Electric Co., however, send us a brief history of the "Osram" lamp, from which it appears that it was commercially introduced to the English market in the early part of 1907. It was then only possible to make it for use on circuits whose pressure did not exceed 120 volts and of candle power not over 50. This necessitated the lamps being restricted to low-voltage circuits, except in instances where they could be run two in series on high-voltage mains. For house and shop lighting a 50 c.p. lamp was sometimes found to provide too high an illumination.

The huge factory that has recently been erected at Hammersmith for the manufacture of Osram lamps is now employing over 1,100 hands, so that it is evident rapid progress has been made; and, after various stages of improvement, lamps suitable for burning on pressures not exceeding 260 volts are now being produced. The company have also been successful in making lamps suitable for pressures up to 135 volts in 16 c.p. and lamps suitable for pressures up to 200 to 260 volts as low as 25 c.p. This has enabled the Osram lamp to be used in practically any building where the old form of carbon lamp has already been at work. It might be of interest to point out that the Osram lamp has now been brought to such a stage of perfection that the current consumption is only approximately 1 watt per candle-power, which is about 75 per cent. less than that taken by carbon filament lamps—in other words, an Osram lamp only takes approximately one-quarter of the current of a carbon filament lamp.

The Osram lamp, it is claimed, is unaffected by vibration, and these lamps have been used for a considerable time in all the leading railways in England as well as in the colonies. Also in many instances Osram lamps have been used, with great success, fitted in clusters on fittings suspended from tramway poles. They are in use for street lighting at Hampstead, Hammersmith, Marylebone, Wimbledon, Canterbury, Exeter, Acton and many other towns, no complaint being received from these places that they do their work inefficiently. The great efficiency and the long life of the lamps have, in fact, enabled the Corporation authorities, we are informed, to compete successfully with gas, and in most instances the corporations are able to show a great saving in yearly cost after receiving an increased illumination. The life is three or four times as great as that obtained from carbon lamps.

Amongst recent installations where Osram lamps have been utilised mention may be made of the Maida Vale Skating Rink, the London Hippodrome, the People's Palace (Mile End), the Empire (Leicester-square), the Theatre Royal (Hanley), Stoneleigh Abbey, Cobham Hall, the leading London stores (Messrs. Warings, Harrods, Selfridges, &c.), certain sections of the Houses of Parliament, the Law Courts, Wormwood Scrubbs Prison, as well as most of the leading hospitals, asylums and many churches and other places of worship.

The English factory of the Osram lamps has, we may mention, already proved too small for these requirements, and rapid extensions are being made to cope with the demand. Osram lamps can now be had in all sizes from ½ c.p. to 1,000 c.p. The 400, 600 and 1,000 c.p. lamps have quite taken the place of the old arc lamps in many instances.

A "Tantalum" Advertising Campaign.

Though all readers of The Electrician are, of course, convinced of the benefits obtainable from the use of metal filament lamps, there are others of the inhabitants of these isles who are living in outer darkness from this point of view. To change this state of things a vigorous advertising campaign is necessary. The advantage of metal filament lamps must be blazed forth from hoardings, railway carriages, roofs, "front pages," and any other places which come immediately under the notice of the general public. Messrs. Siemens Bros. Dynamo Works have heartily undertaken this spade work. "Tantalum" lamp advertising has, in fact, always been distinctive and effective. Contractors and the trade generally will doubtless be glad to hear that this year Messrs. Siemens Brothers Dynamo Works have arranged for a wider and more comprehensive scheme than in the past. In addition to their usually large scheme of trade paper advertising, some newspapers will also be included. We reproduce herewith (Fig. 1) an illustration of the new design of "Tantalum" lamp show card. The design is one of the "Satisfied Consumer" series, and is a follow-on to that well-known poster, "My Electric Light Bill Halved." It is of small size, 12 in. by 9 in., printed in five colours, with the main features embossed, the lettering being glazed to make it stand out very prominently. Posters of the same design—80 in. by 60 in. and also 120 in. by 80 in.—will be supplied to any person who has a suitable space for displaying them about his premises.

The same firm are also supplying a five-coloured card giving reduced facsimiles of all the types of literature which they overprint in quantities with the contractor's name and addresses free of charge. These include post-cards and three or four types of adhesive labels for attaching to correspondence. We should like particularly to draw attention to the picture post-cards. These are all printed with the same design, while on the back the contractor's name and address can be overprinted, so that they may be used as correspondence cards. The adhesive labels are well-known and widely used, the latest production of the firm in this direction being a "sticky-back" in the shape of a "Tantalum" lamp, which has been lithographed in colours and on which the words "Use 'Tantalum' Lamps" appear. By fixing these to all outward correspondence contractors can obtain an effective method of advertising "Tantalum" lamps. A reprint of the well-known Hassall design, the "Brilliant Passage" stamp, has been obtained, and these will again be supplied during the forthcoming season. A reprint has also been obtained of the Dalston Works adhesive labels, and these will also be supplied to all who desire to attach them to their correspondence.

Fig. 1.—New Design of "Tantalum" Poster.

With reference to "Tube" railway advertising, a very wide scheme has been arranged. Many people have noticed the present card in the trains which states "Watch this Space for 'Tantalum' Lamps," and there are thousands of people who are on the look-out for the design which is to appear in the space indicated. Large posters are also appearing on the majority of the London tube and railway stations. We think such an extensive scheme of railway advertising must reach many people who are actually using electricity as an illuminant. In connection with poster advertising, Messrs. Siemens Bros. have arranged a very extensive programme, and posters will appear on many hoardings in all the large provincial towns, whilst in and around London there will also be a representative display. In conjunction with these large schemes of general advertising to the public, there are also several special schemes by means of which consumers will be approached direct. Although the sales of "Tantalum" lamps have been steadily increasing during the present year, yet under such a wide publicity campaign they must be still further increased. Messrs. Siemens suggest that all contractors should take advantage of these generous offers, and we may also be permitted to suggest that this very enterprising firm should be supported in their campaign in favour of a wider use of electric lighting.

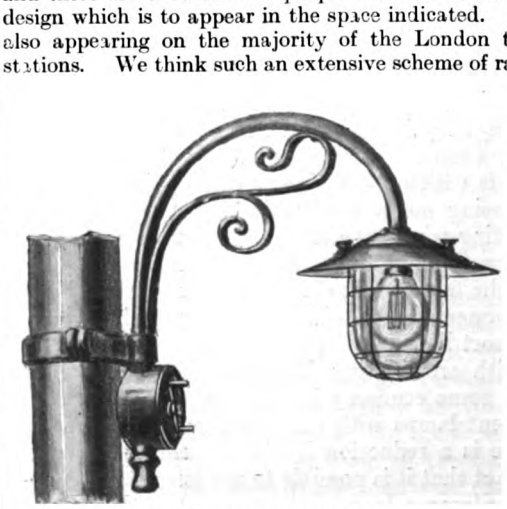

Fig. 2.—Street Lighting Fitting, with 100 c.p. "Onewati" Lamp.

Digitized by Google

Our illustrations (Figs. 2 and 3) show "Tantalum" lamp fittings of two kinds, from which it will be seen artistic design is combined with general utility. It may also be of interest to mention that the filament used in "Tantalum" lamps is stronger than mild steel of the same gauge. With regard to recent installations, "Tantalum" lamps are now being employed for the lighting of many of the City & South London Railway's carriages, and the complete change-over to the new lamps is being undertaken as quickly as possible.

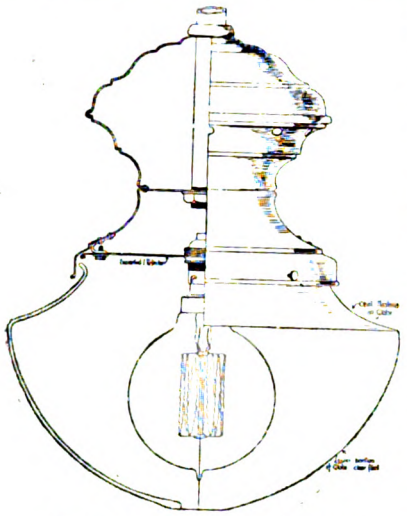

FIG. 3.—LANTERN FOR 100-WATT "ONEWATT" LAMP.

Messrs. Siemens also inform us that they have scored a notable success with their drawn tungsten "Onewatt" lamps. These have in many cases displaced gas, a state of things which is not surprising considering their strength and that they only consume 100 watts.

As regards the lamps themselves, "Tantalum" are now being made in all candle-powers from 5 to 50 and for all voltages between 20 and 250. They are made in several different types, including candle, tubular and focus lamps. The "Onewatt," besides being specially designed for use with batteries—that is, for burning on voltages from 4 to 8 volts and in candle-powers from 3 to 6—is, of course, made in moderate sizes of 10 c.p. and 16 c.p., and in the large sizes of 100 c.p.

B.T.-H. EXPERIENCE.

Anyone who has followed the development of the electric lamp from its inception until the present time will have noticed that the changes and improvements, though few, have been of a very important and distinctive nature. Doubtless this shows that we may still expect substantial improvements.

The last few years have witnessed what is undoubtedly the greatest advance ever made in electric lamps, and it may be said that the metal filament brought about the dawn of a new era in lighting. Certainly the "Mazda" lamp manufactured by the British Thomson-Houston Co. is an excellent representative of the new type of lamp which is now becoming so deservedly popular.

FIG. 4.—50 C.P. "MAZDA" LAMP.

The problems involved in the metal filament have been exceptionally difficult, and it may be said that the essence of inventive genius and modern manufacturing skill available to the large lamp manufacturers of the world has been recently concentrated upon the difficulties involved. We need scarcely remind our readers that the mere manufacture of the filament itself is a very difficult matter when it is considered how exceedingly fine is the wire employed. Owing to the fineness of this wire and the refractory nature of the materials, there has been great difficulty in making filaments of sufficient strength to withstand everyday use. Experience, however, has shown the way to surmount these difficulties, so that the filament has become stronger as time has gone on. Certainly one of the most remarkable achievements is the drawing of such filaments instead of the use of sintering processes. The "Mazda" lamp is one of those in which a drawn filament is used, and we think we are right in saying that the British Thomson-Houston Co. were the first to place such a filament upon the market.

To their many advantages of convenience, safety, adaptability, low maintenance cost, cleanliness and reliability, Mazda metal filament electric lamps have added a threefold improvement in efficiency. In addition to saving over 70 per cent. in current consumption, they give a most agreeable and attractive light, approaching to sunlight in its clearness, whiteness and healthfulness.

With all its many advantages its true economy, its long useful life and inexpensiveness, it cannot be denied that the Mazda lamp is one of the most efficient and best forms of lamp to use wherever artificial illumination is required, whether in the home, factory or workshop.

SOME EXPERIENCES WITH "AEGMA" LAMPS.

The Electrical Co. inform us that their lamps are now being pushed forward for street lighting purposes, and are being used at

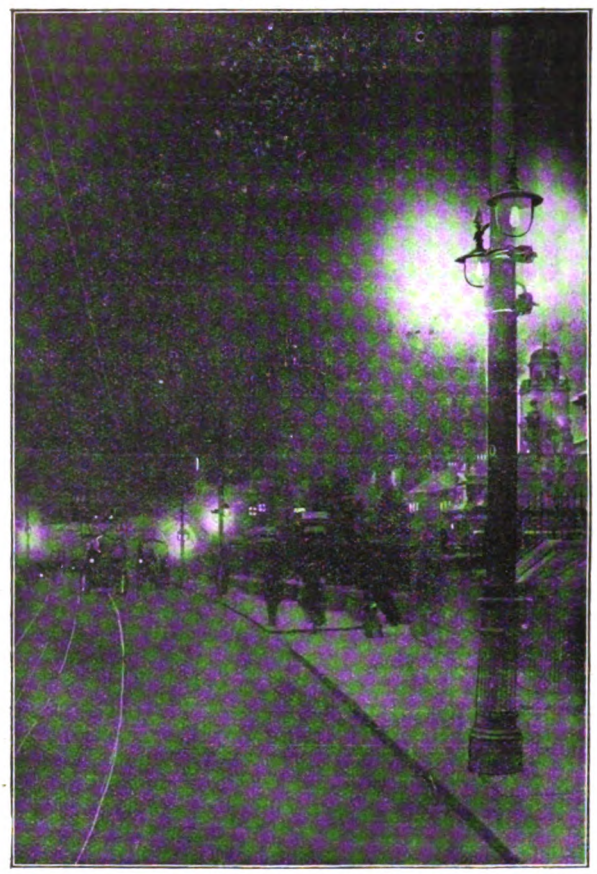

FIG. 5.—"AEGMA" LAMPS AT NIGHT.

many towns in the United Kingdom, amongst which we may mention Barnsley, Brighton, Barnes, Colchester, Gillingham, Gravesend, Portsmouth, &c. Excellent results are being reported. At Colchester there are 250 fittings which contain two 210-volt lamps burning in parallel. The life of the lamps at this town has given, we understand, every satisfaction.

At Eccles some 300 50 c.p. lamps have been in use for the past 15 months, burning approximately 3,800 hours per post. An average life of nearly 2,000 hours has been obtained at this town, though the voltage is 200 alternating.

Barnsley also report, we understand, very satisfactory results, although at the moment no actual figures are obtainable; but the lamps installed have burnt well over 1,000 hours, and most of them are still in service.

The all-important point of delivery must not be overlooked. The Electrical Co., in fact, have made arrangements this year for carrying a huge stock of lamps in London, and with this stock in London and with the works behind them turning out 30,000 lamps per day, they can with assurance guarantee immediate despatch, not only in September, but throughout the whole season. The works have been extended con-

FIG. 6.

Digitized by Google

siderably, and are now said to be one of the largest in the world, having a daily output of between 25,000 and 30,000 metal lamps.

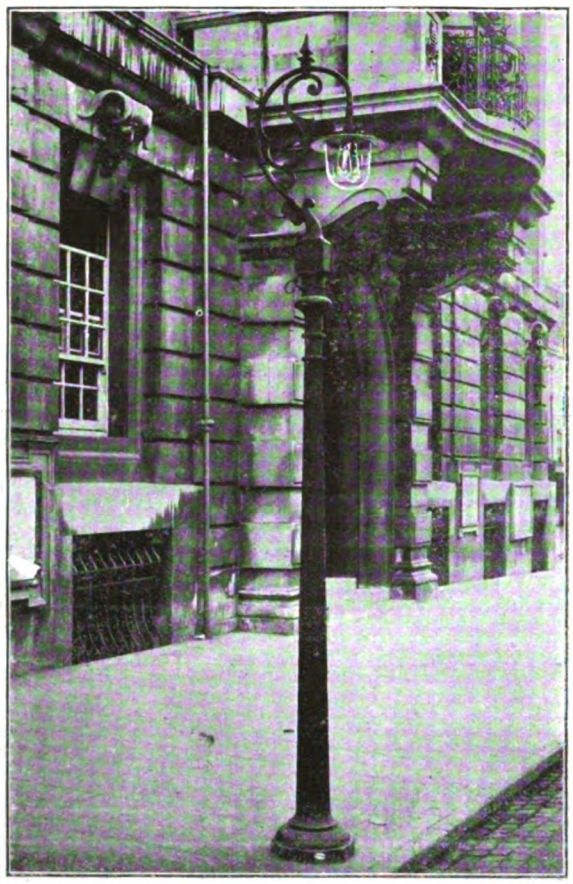

FIG. 7.—STREET LIGHTING FITTING AT COLCHESTER.

The candle lamp, shown in Fig. 6, is a new addition to their list. These lamps are made in 5, 10 or 16 c.p. for pressures varying from 20 to 130 volts.

"LEUCONIUM" LAMPS.

The "Leuconium" lamps, which are manufactured by the Stearn Electric Lamp Co., are made in all shapes and candle-powers. Special mention may be made of the low candle-power high-voltage lamps which are a speciality of this Company's manufacture. These are supplied in three candle-powers (16, 18 and 22), and are suitable for burning on all voltages up to 250. The ordinary metal filament lamps for the usual voltages and candle-powers are also supplied. Mention may also be made of the "Leuconium" cluster lamp, made up of five tubular units containing one or two filaments, according to the voltage. These are connected in series, and the tubes can be renewed at a very small cost, thus effecting a great economy over the usual method, where if one filament breaks the whole lamp is useless.

"MASCOT" METAL FILAMENT LAMPS.

One of the greatest difficulties with which all manufacturers of metal filament lamps are faced is the spacing of the many filaments which must necessarily be used for high-voltage lamps. When it is realised that for metal lamps five times the length of filament must be used as for carbon lamps of equivalent voltage the reason why such large and unsightly bulbs were at first used in the making of these lamps becomes evident. The size of the bulbs was strongly objected to by the consumer, so makers were obliged to reduce the size, and this entailed the placing of filaments closer together. However, as is so often the case, one difficulty was overcome only to encounter another. It is generally admitted that the chief cause of failure with the high-voltage lamp is caused by the short-circuiting of the filaments, which creep together when burning, thereby cutting out whole sections and over-running the remainder of the lamp, thus considerably shortening the life. To overcome these difficulties Mr. Horvath, of Southfields, has designed the "Mascot" lamp. By an entirely new arrangement of filaments, for which he has been granted a patent, it is now, he claims, practically impossible for the filaments to be drawn one to the other. They are arranged on a double frame in two rows, one circle of filaments being placed directly inside a larger or outer circle, thus enabling each filament to be spread out to twice the usual width at its base. Such a saving of space is effected by this arrangement that a 25 c.p. 200-volt lamp is mounted in a bulb very little larger than a 16 c.p. carbon lamp of equal voltage.

FIG. 8.

Mr. Horvath has also patented the "Metaflect" lamp. This is a combination of a tubular metal filament lamp and reflector. The tubular lamp is fitted with a special cap having ventilated holes. It is made suitable for pressures up to 55 volts and the lamps are grouped in series for running on high voltages. The reflector consists of a flattened oval glass bulb, one side of which is silvered, and which cannot easily tarnish or oxidise, the actual shape of the reflecting surface being a special feature of this lamp. Whilst distributing a good general light at a wide angle, it also gives out a concentrated light of high value; in other words, 60 c.p. may be obtained from a 12 c.p. lamp in a concentrated beam. Another advantage consists in being able to direct the light to any desired spot merely by turning the reflector round in the lamp gallery. The accompanying illustrations show two cheap forms of fittings suitable for use with these lamps. That in Fig. 8 consists of a thin tube with four short arms on to which the "Metaflects" are attached. This can be fixed into the corners of shop windows and similar positions. Fig. 9 shows a ceiling fitting with arms set at an angle so that the light is well distributed over a large area. When this is realised it is readily understood what enormous possibilities this lamp has for shop lighting, show-cases, concealed lighting and many similar purposes.

FIG. 9.—GALSWORTHY'S REFLECTOR FITTING.

The sale of these lamps and the "Mascots" is in the hands of Messrs. Galsworthy, 15 and 16, Newman-street, London.

BRIMSDOWN LAMPS.

The Imperial Lamp Works, of Brimsdown, are now making colloid-tungsten lamps, which are, it is claimed, second to none in strength, reliability and efficiency. They can be supplied with either pear-shaped, round or candle-shaped bulbs, suitable for burning on all pressures up to 260 volts and in candle-powers from 9 to 900.

"METALIK" LAMPS.

The "Metalik" lamps made by Messrs. G. M. Boddy & Co. have also been receiving an extended application during the past year. They are now in use for street lighting in both St. Paul's Churchyard and Queen Victoria-street, while, as examples of places where they are being used for other purposes, we may mention Messrs. Pawson & Leaf's works and "The Times" office.

Earth Wires to Telephone Lightning Arresters.—The "Electrical World" states that it has recently been decided in the Courts that it is negligence for a telephone company to fail to have its lightning arresters equipped with earth wires. The plaintiff was using his telephone in the ordinary manner when lightning struck the instrument and inflicted injuries for which he was awarded £1,000 damages. The evidence showed that there was no earth wire attached to the lightning arrester on the telephone in question.

THE RELATIONS OF SCIENCE TO INDUSTRY AND COMMERCE.*

BY R. BLAIR.

(*Concluded from page 936.*)

Summary.—The author in dealing with this subject gives an abstract of the views of students, university teachers, manufacturers and consuls on the present connection between science and industry. It is shown that, while matters are improving, higher education is of too theoretical and detached a nature to make its recipient immediately useful in the commercial world. Remedies to counteract this state of things are suggested.

It is impossible to ignore the unanimity of the story told by H.M. consuls. The main question submitted to them was as to whether there was any truth in the statement that British firms did not sufficiently apply scientific methods to the canvassing of foreign markets, that their agents did not know the language of the country in which they were working, and that generally there was a want of activity and enterprise of the right kind. This indictment seems to be to a large extent true. British manufacturers having had till about 30 years ago rather more than their share of the world's trade made money so easily that they relaxed their efforts and have not yet adapted themselves to altered conditions of strong competition from Germany and the United States. There is not enough co-operation amongst the smaller firms, while there is a distinct lack of enterprise in sending out travellers, the number not the quality being at fault. Until by scientific education the British realise that commerce means an intricate and complex organisation of intimately inter-connected parts, they will lose many an opportunity and their consulates and chambers of commerce will be unable to do for them the work which could easily be done. Engineering, it is pointed out, is looked upon as a science, but commerce is not. Failure to adopt the metric system and to print catalogues and price lists in the language of the country in which it is intended they should be circulated is another reason why more progress is not made. Enough stress cannot be laid on the vital importance of personal acquaintance with the country, the people, their customs, needs, weaknesses, likings and prejudices and also with the local methods of doing business—in short, with everything and anything that can and does affect the market.

If the requirements of any country are to be thoroughly understood, a knowledge of the language of that country is essential. Much stress is laid by the consuls on the importance of this point, which aids in no uncertain manner the worker and the seller of goods. In this respect the English system of teaching languages is much at fault and a case is called to mind where children of a consul, who were able to converse comfortably in four or five languages, on being sent to an English school, promply forgot all they knew in this direction, though two of the said languages were in their regular school course. Too much attention seems to be paid to the learning of grammatical rules and not enough to conversation and other methods of adding to their vocabulary.

In fact, although the universities have done great work in the formative life of this country the modern world needs something more, especially from the departments of applied science. More is to be learnt from American than German methods, for there it is realised that whatever training of the highest kind a man may have he must still begin in the ranks and climb his way to the top. It has been said that British character and methods produce a few brilliant units and a mass of mediocrities. The surest road to success would probably be for the mass of mediocrities to adopt the methods of the brilliant units.

The normal attitude of the employers, if not of the public, may be expressed in three sentences: (1) Only those value higher education who have felt the need for it. (2) The purely practical man can do much, the purely theoretical man can do little; a combination is therefore necessary. Should one quality only be obtainable, which would be regrettable, that quality should be the purely practical. (3) Teaching institutions may assist individuals to get on; they form no essential part of our industrial or commercial system.

For these three sentiments I suggest that we are all anxious to substitute three others: (1) Setting aside exceptions, every man who achieves success must give a certain amount of time to fit himself for his work, whether the time is given in college under guidance and discipline, or is expended in self-education. (2) In the end, and again setting aside exceptions, the man who has received the highest training in college under guidance and discipline will, other things being equal, achieve by far the greatest success. (3) The work of research and training as carried on in technical school and university college is an integral part of any nation's successful industrial and commercial organisation.

How is the substitution to be accomplished? The demand of the shareholders of an industrial or commercial concern for dividends forms a great stimulus to intelligence and activity on the part of the staff. Without such stimulus in a technical school or faculty of applied science, there is a tendency for things to become too comfortable.

I suggest the following:—The management of all technical institutions and departments of applied science should, therefore, be put on a business footing. The ordinary governing bodies, as a rule, serve for ordinary governing purposes. The chief need is that of consultative committees attached to all specialised faculties or departments, such committees to be advisory and to be composed of industrial or commercial leaders or experts of the highest reputation. This is probably the best and surest means of enlisting the full sympathy of industrial and commercial leaders. The faculty or department, the curriculum and the examinations, would benefit by having its work and methods criticised sympathetically by experts of the first rank. Such a committee would form the surest medium of communication between the college and the workshop; and its formation would certainly be followed by a wide extension of the appreciation of the advantages of technical education because the captains of industry would learn exactly the character of the work done in college and how in practice to utilise it. The head of the teaching department and his staff would by this means gain easy access to factory and workshop, and bring back some of the atmosphere to the laboratory. On the examining committee of the engineering department of the Glasgow & West of Scotland Technical College are the engineering director of the Fairfield Shipbuilding & Engineering Co. and the engineering director of John Brown & Co., Clydebank Shipbuilding & Engineering Works. Such men would probably be generally recognised as the leaders in their particular profession on the Clyde. I understand that it is their practice to look in great detail through worked papers and designs and to give the engineering department of the college the benefit of their criticisms. Employers, parents and students cannot but have faith in the instruction given in an institution so aided. Let me make it quite clear that I am not advocating a mixed governing body, but an advisory committee of experts attached to each technical department. Governing bodies should consult such advisory committees before appointing the head of a department or even the principal of a college or technical institution. In the qualifications of principals and heads of departments it is customary to give too much consideration to academic status and too little to industrial experience and business capacity. Such a consultative body as I have referred to would act as a corrective in this respect.

A connection should be maintained with old students and a record kept of their after careers. One of the means of success of the American colleges is the list of after careers of their students. It is almost incredible how little has been done in Britain in this respect. I hope parents and the public generally will develop a habit of asking for such a list.

At each technical institution and university there should be an organisation to assist students in getting placed. The Blue Book recently issued by the Board of Education shows how much English universities have in the past neglected this aspect of their work and how much there is still to be done to establish appointments committees or bureaux. I am not overlooking the fact that much excellent work has been done by individual professors and occasionally by the secretary or the principal. But this was unorganised. I am asking for an organisation. The manufacturer and the merchant have been denounced in no measured terms by representatives of learning for their short-sightedness in not applying scientific methods to manufacturing and business processes; could not the manufacturer and the business man retaliate that not only have university and technical college goods been of such various qualities that it is impossible to discriminate, but also that scientific principles—even common business empirical methods—have not been applied to the marketing of school and college products? It is a discredit to the universities and technical colleges that they have so long neglected this obvious means of assisting students, this obvious means of promoting the cause they proclaimed.

A change in curriculum and in degree requirements. Let me read some remarks on American colleges which I wrote in 1904:—"Again, there is in each American institution a considerable 'mortality' or shedding of students. Some students find their general preparation insufficient; some find the pace too great; others find their funds give out; and some are advised that they have made a bad selection. In such cases the American student accepts advice, and acts promptly. At every step a student's work is known, and the faculty—staff of professors in each department—every four

* Abstract of a Paper read before Section D of the British Association.

Digitized by Google

months discuss fully a student's work. The middle of the third year is the critical point in a student's career. At this stage the requirements of the Institute of Technology demand a final decision as to choice of work. Fifteen men in one department were, at this point, recently advised to change their courses or to withdraw from the institute. I was informed that, as a rule, 25 per cent. of the civil engineering students drop off at the same stage. These numbers have to be added to those who have previously 'fallen by the way.' The greatest patience is extended to the students, and the best advice is offered to them; but in the interest of the individual, as of the standing of the institute and of its influence on industrial work, such shedding of students is regarded as inevitable, and is acquiesced in. It does not follow that the men are 'wasted.' As a rule they find employment of a lower character than they were aiming at; they change the directions of their careers to their own great advantage; or they pursue a course of studies on the same lines at a secondary institution—a two-year course school."

It appears to me that such kind of advice and action is necessary in British teaching institutions, but it can hardly be done under existing conditions.

Another means of bringing the college classroom and laboratory nto closer connection with factory, workshop and office would be more liberal provision of short, cheap and specialised courses, suitable to the heads of firms or their successors. I am not referring to that provision of evening courses which is made in technical schools and schools of art, but to provision, whether day or evening, of advanced courses for industrial and commercial leaders or their successors in institutions which there could be no presumed loss of self-respect in attending. Such courses are provided at several colleges; they need multiplication. I know that a large number of able men obtain, at much expense, instruction through private agencies because the best institutions do not appear to cater directly for their needs under suitable conditions.

As to modern languages, three things are necessary for the majority of students: (1) Less the scholar's and more the utilitarian point of view. (2) More concentration during the later school and college years. (3) Speaking generally, a better class of teachers.

In conclusion, let me say that this preliminary study of a very large question has disclosed much hopefulness for the future. The obstacles which university and other highly trained men encounter in getting a footing in the industrial world are still formidable; and the breaking down of the barriers between our highest teaching institutions and commercial life forms a specially difficult task. But there is plenty of need for first-class men, and there is not much difficulty in getting the exceptionally good man placed. It is gratifying, too, to find that His Majesty's consuls speak in the highest terms of the personal qualities of our foreign commercial travellers.

On the side of education, too, there is much hopefulness. A distinguished university writer not long ago stated that the object of university education "was not how to keep our trade but how to keep our souls alive." Between such a representative of university education and the business man who inquires what is the money value of a degree, there is little room for accommodation. But the writer did an injustice to the universities, and the facts as to the objects of university education are against him. It may be true that in the long view the keeping of our souls alive is the object of university education, but even the oldest of our universities are becoming conscious that the immediate condition of saving our souls alive is that of saving our trade.

DISCUSSION.

Dr. H. T. Tovey, F.R.S., said he knew that in many works the principles of science were taken advantage of, and skilled men of ability were employed in testing the output and keeping it up to the standard, and also in experimenting with new methods. He was strongly of opinion that the application of science to industry should be universal. He thought the reason of the neglect of the possibilities of its application might perhaps be found in the lack of organisation of our national resources as applied to the training in technical knowledge and skill. He advocated the organisation and centralisation of technical education.

Dr. Griffiths (Cardiff) remarked that they had definite data now to work upon. The Paper convincingly showed that there was something very unsatisfactory in the present condition of things. The speaker could sum up the whole case in one sentence—want of communication—the extraordinary aloofness which existed between the men who conducted the universities and the men in the market place. It was not a want of sympathy, but a want of communication. The great question was how they should establish an easy means of communication and an interchange of views. There were faults on both sides. They had seen a good deal of the professors denouncing all the business communities. But looking at the matter dispassionately he fancied that business men knew their own business better than did the professors. If they (the professors) had not been able to find out yet exactly what these business men wanted there was no use in continually anathematising them. It was their business to try and find out what these men wanted and to see if they could supply it. He did not think that business men had given the system a fair trial. He believed that the man of business was in the habit of looking for immediate results. No one could guarantee that technical training, however excellent, would have that effect. Nor could they turn out from the technical institutions men who were fully acquainted with all the intricacies of the workshop. It was the business of teachers to instil into the students principles which they would afterwards be able to carry into practice. He did not believe that the business of the workshop could be taught except in the workshop. A fault of the teachers had been that purely scientific men insisted too much on technicalities of their own. They did not enter sufficiently into the points of view of the man in the market place. The top and bottom of the whole business was that at present the people did not believe in science. They believed it should be encouraged in an academic kind of way. But he did not think the British manufacturer in his heart believed in science. And no amount of talking would alter this. They must bring home to the people the advantages of research, the advantages they had gained from the laboratory in the past—advantages which to business men represented hard cash, and which to the people at large meant health and happiness. They must teach them what they had profited from a man like Faraday; what they had gained in the matter of health from Lister; they must teach them how such work as the building of the Panama Canal was done in the laboratory—largely through a close and almost indecent examination of the mosquito. They must in this way bring home to the people the advantages of pure science and their manufacturers would soon wake up. They would not attain their end by abusing industrial men, but by educating the people. The author had spoken of the preference of some manufacturers for the lad from the elementary school. In South Wales the view held was quite different. He heard one manufacturer say they were good for nothing except to lick stamps. They could not spell, they could not write, and they most probably did not know what the capital of France was.

Dr. Bielby (Glasgow) said the keynote of Mr. Blair's communication was one of hope. He agreed with Mr. Blair that it was necessary to educate the manufacturers, to educate the public, in fact, and he strongly supported the suggestion in favour of co-opting business and commercial men on the committees of their colleges and universities, thus bringing about better means of communication between those institutions and the men in the market place.

Sir Wm. White said he did not believe that in the application of science to commerce and industry we were so far behind other countries as was often asserted. There were directions in which this country led, and, of course, directions in which other nations had the lead, but, taking the position in the aggregate, we did not compare badly. We were not organised so thoroughly as was the case in some other countries, but it was possible to carry organisation too far and paralyse effort, and that had been the result in some cases abroad. There seemed to be a general impression that if a young man received a high technical or scientific training, he was at once fitted to apply his knowledge in practical work or manufacture. But that was not so. In engineering there were many young men who could get through the theoretical side of their training with complete success, but who would never be engineers, because they did not possess the necessary practical tendencies. This was, unfortunately, discovered too late, and therefore it was that a committee on engineering education, over which he presided, advised that a certain period of experience in shops should precede the advanced theoretical training, in order that, if it was found that young men did not possess practical capabilities, they might turn their attention in some other direction. There was a tendency on the part of those who had been scientifically trained to treat the business man and the manufacturer as if he only needed to be told what he had to do. Now, they might take it for granted that these men did know their own business best, and that they resented this attitude. When they got a man fresh from a scientific institution, who had been admitted into a works as what was really an improver, assuming the attitude that not a few misguided young men had assumed within his own personal knowledge, it was not to be wondered at that he did not go on and make a position. They wanted a better understanding between those who studied science and those who were concerned in its applications, and that understanding was not to be attained by telling the men who were engaged in the practical side of the business that they knew nothing and wanted to go to school again. He agreed with the suggestion that post graduate courses should be taken, but he could not help thinking that, on the whole, they were best taken, for many branches of industry, in the works themselves. He strongly advocated the multiplication of research laboratories in the works. He quoted a striking instance of the success of this system—how, as the result of research in the laboratories at Essen, based on Sir Wm. Roberts Austen's classical researches in the heat treatment of steel, a process was devised which had been enormously profitable to Messrs. Krupp, chiefly in the manufacture of armour. From that time onwards, they had received royalties which had repaid them a thousand times for what they had spent in the maintenance of the laboratory. Mr. Blair had referred to the statement that British character and methods produced a few brilliant units and a mass of mediocrities. He (the speaker) believed that in this matter, as in all others, there must be a process of natural selection, and that, in order to discover those who would be leaders and captains on the scientific side they must be content to train a great many, the bulk of whom would not rise to the highest standard. The waste was only apparent, because any man was made all the better for whatever walk in life he might follow by attaining greater knowledge.

Mr. J. E. Stead, F.R.S. (Middlesbrough) uttered a protest, so far as metallurgists were concerned, against the idea that science was neglected.

Digitized by Google

He said manufacturers of steel did recognise very fully the value of original research. At present, however, they had got into the state of wanting a little too much in too short a time. Manufacturers must not demand so high a standard. They ought to be satisfied with a man who was thoroughly grounded in education, and prepared to let him supplement that education by a couple of years' training in their own works.

Prof. ARMSTRONG (London) remarked that the university system could be supplemented by the works laboratory. He agreed with Sir William White that we in this country were not so far behind as we were painted to be, and if we could organise our forces more thoroughly we should get better co-operation and better results.

Sir W. TILDEN, F.R.S., (in a written communication) spoke of the general scientific ignorance of employers and employed, especially in the chemical and electrical industries. He contended that not only employers, but also the State, were largely to blame for the present neglect of science by commerce and industry. From the members of the present Cabinet downwards, it would be difficult to find in Whitehall any official holding a superior administrative post who had received an education of which physical science formed any substantial part. Heroic speeches were delivered in Parliament in regard to the importance of science, but the measure of Parliamentary interest was shown by the extremely moderate character of the grants made to the universities. As a matter of fact, the new Imperial College of Science and Technology was inadequately endowed.

THE FIRST DECADE OF MUNICIPAL TRAMWAY WORKING.*

BY ALDERMAN S. FLINT.

(Chairman, Leicester Corporation Tramways Committee.)

The author here confines his remarks to municipal tramways. At the present time there are in this country 176 tramways owned by municipalities, only 84 of which, however, are worked by the same authority that owns them, and it is with these that I am only going to deal. The statistics I have prepared are as follows:—

	1899.	1909.
No. of undertakings	6	81
Miles of track	52	2,422
No. of cars	197	7,986
No. of miles run	3,371,806	197,938,433
No. of passengers	38,432,470	1,933,118,206

These figures show an enormous increase of municipal ownership and working in 10 years, and it is very doubtful if it would have been as great and as rapid under private control. As to the financial aspect, I will call your attention to some further figures.

	1899.	1909.
Capital invested	£697,270	£40,436,350
Annual income	179,585	8,780,542
Annual expenditure	112,093	5,487,291
Amount paid in interest	20,597	1,150,905
Amount paid in sinking fund	16,907	1,005,758
Income tax	848	54,026
Sundries	1,432	107,713
Net profit in year	£32,927	£974,949
Disposed of as followed:—		
To reserve fund	£26,762	£750,176
To relief of rates	6,167	303,412
Less paid out of rates	5,211	78,639
Total reserve fund to 1909		£4,200,462
Total to relief of rates to 1909		2,481,760
Total to sinking fund to 1909		6,619,450
		£13,301,672

I make no point here of the amount paid in interest during the past 10 years, because any private company would have had to meet the same charges, but I do say that the thirteen millions would have been available for dividends to shareholders, and further that the six millions placed to reserve and to the relief of rates might have been added to the sinking fund, had the various corporations so willed, and to that further extent would have reduced the liabilities under that head. But in my opinion every corporation would have been well advised in placing all net profits to reserve until there was amply sufficient to meet every emergency that might arise, and so make it practically impossible for any claim to be made on the rates. I am afraid that some of our committees will find they have made a mistake in handing over large sums to relieve the rates except in those cases where there is already a large reserve fund. I am well aware of the temptation and the pressure brought to bear, but in some cases, at any rate, it should have been resisted. I may be reminded of the amounts that have had to be paid from the rates to meet capital charges. Well, that is somewhat of a set-off, and not to be omitted. I have not the actual figures, but do not think it would reach nearly half a million during the 10 years.

In nearly all the towns that have shown a deficit, it will be found that their power costs are very high, or that they have but small populations. It will also be found that towns with separate power stations show better results than those with combined power and lighting stations, that is, where tramway committees have to buy their current. It is, perhaps, a delicate point for me to touch upon, but I doubt whether it was wise to start tramways in some of the very small towns, where the population is not sufficiently dense to make them pay either under public or private control. If, however, the people, with all the facts before them, are prepared to pay adequate fares, or even a small rate, then we need not complain. Anyway, such cases do not in any degree vitiate the policy of municipalising the tramways. That policy has been amply justified by the results, and the above figures show that the municipal tramways of the country are in a sound financial condition, and need not cause the ratepayers any fear or misgiving, except in a few isolated and unimportant cases. I am certain of this, if there was the least desire to sell them, either separately or *en bloc*, they could be sold at a handsome profit, and that is a fair test of their value. I may also remind you that many tramway undertakings have had to bear all or part of the expence of valuable street improvements, in some cases improvements that were not really necessary for tramway purposes.

The author next refers to the improved conditions enjoyed by all classes of tramway employees. These improved conditions have no doubt been facilitated by the introduction of electric, for horse-drawn cars, but it is very doubtful if they would have been granted to anything like the same extent by private or company undertakings. It may fairly be claimed that this Association has contributed in no small degree to the success of this policy. The progressive and enterprising spirit of the various committees, managers and engineers has also done much to popularise the municipal tram services. An important point to consider is what can be done to make our trams still more useful and popular, as we have not yet reached finality, although there seems to have been a lull lately. Reasonable care, however, must be taken not to make doubtful or risky experiments. I venture to suggest, as I have suggested at previous conferences, that an effort should be made to secure some degree of uniformity in regard to wages and conditions of tramway men.

Although nearly all the large municipal undertakings are in a sound financial position, some are not so placed. Whilst every tramway committee, through its manager, should keep a strict eye on its expenditure, I consider it equally important to try and increase the revenue. There is ample scope for improvement in this direction. Conductors require to be further educated in the matter of looking out for passengers, and motormen also must be trained to avoid waste of current. The difficulties of some undertakings have been caused by the price they have to pay for current. The ideal arrangement, of course, is for each tramway committee to generate its own current, especially in large towns. Where this is done the undertaking is found in a good financial position as a rule, but in small places, and even in large towns where there is a combined station and where the tram committee has to purchase the current, the price should be fixed at a reasonable figure. Where this does not prevail the committee should persistently press for a reduction of the price per unit.

Another common mistake is to run more cars on a given route than is justified by the needs of the district, resulting in very low receipts per car-mile. The old custom under which all tramway committees have to keep in repair the centre of the track and 18 in. outside the rails is also one that calls for reconsideration and revision. A first step should be to relieve tramway committees of the duty of maintaining the 18 in. outside the rails. The wider question might then be left for open a time. One point more I should like to suggest for consideration, viz., that wherever there is a desire for co-operation between adjacent towns it should be fostered and encouraged, and especially when overtures are made by county authorities for joint action with the borough authorities. I believe there is a large amount of good to be done in that direction, although care must be taken to protect the interests of our corporations and the ratepayers in the boroughs.

Included with the Paper are several tabulated statements, these give statistics of municipal tramway undertakings in 1899 and 1909, a comparison of the wages, hours of labour, &c., on the Leicester tramways in 1899 and 1909; a list of towns with combined power stations and the price paid per unit for tramway current, a list of towns with separate power stations and the total cost per unit, and lists of towns showing the financial results obtained.

* Abstract of a Paper read on Wednesday at the Conference of the Municipal Tramways Association.

The Rates for Subscription to "THE ELECTRICIAN" are as under:—

	Year.	Half-Year.	Quarter.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Canada	28s. 3d.	14s. 6d.	7s. 6d.	
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	

New volumes of "THE ELECTRICIAN" *commence in April and October.*
(This charge includes all Supplements.)
Vols. I to LXIV. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Dec. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s.; Europe, 2s.; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription, 5s., post free.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three Separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.
VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free,

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A Fleming. Vol. I., 12s. 6d. nett. Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms, bound strong cloth. Price 7s. 6d. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d nett.

RADIO-ACTIVITY. AN ELEMENTARY TREATISE FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. C. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. [Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton. M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE TWO-TONE VIBRATING TRANSMITTER AND CABLE INDUCTIVE SIGNALLING. By Edward Raymond-Barker. Price 1s. nett and post free.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. *In Preparation.* [Price 3s. nett.

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *In Preparation.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *In Preparation.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Nearly Ready.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Högner, by Justus Eck. *In Preparation.*

LIVINGSTONE'S DIAGRAM FOR THE EASY CALCULATION OF SHAFT AND BEAM DEFLECTIONS. By R. Livingstone. 2s. 6d. nett. By post, in tube, 2s. 10d. *Now Ready.*

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal, 1861-1878).

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny.
Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON
(ONLY ADDRESS.)

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement is published (Gratis) with the current number of "THE ELECTRICIAN."

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various industrial purposes.

SPECIAL NOTICE.

NOW READY.—Vol. LXIV. of "THE ELECTRICIAN" (1,086 pages), bound in strong cloth. Price 17s. 6d.; post free, 18s. 6d. Now ready. Cases for Binding. Price 2s.; post free, 2s. 3d.

A complete set of "THE ELECTRICIAN" can be supplied. A number of odd volumes and some odd old back numbers, to help in making up complete sets, are also available.

ELECTRICITY *VERSUS* GAS FOR STREET LIGHTING.

At last our gas friends have forsaken some of their vagueness and have actually descended into figures. The reason for their recent reticence can easily be surmised, and the present lapse into figures on their part is therefore the more noteworthy. Where statements are made to the effect that electricity is very many times dearer than gas—the figures varying at the discretion of the writer—the absurdity of the comparison is obvious to the man in the street; but since the introduction of metal filament lamps and flame arcs, gas enthusiasts have been more vague in their statements as to the performance of gas lamps, and have been content to criticise the figures put forward by electrical engineers. The latter have always given the fullest particulars as to the cost and energy consumption of electric lamps, so that gas engineers have had the advantage of knowing the "best" that electricity as applied to lighting can do.

As to possible developments in gas lighting the public are generally given profuse information of a kind, but the great difficulty of verifying statements as to the relative cheapness of gas and electric lighting must not be forgotten. In the case of street lighting this is particularly the case, for

Digitized by Google

it is obvious that the measurement of the gas used in public lighting is no easy matter. This consumption must be more or less conjectured from laboratory experiments, whereas what electrical engineers would like to see are a few figures of gas consumption under actual lighting conditions.

But to return to the figures which have now been let slip by the "Journal of Gas Lighting." Our contemporary has recently been much disturbed by criticisms in the electrical press, and by the London Electric Supply Companies, as to the prices at which the Gas Light & Coke Co. have offered to supply the street lighting in the City of Westminster. The defence has, we believe, been put forward that the Gas Company can please themselves what price they care to charge for the lighting of these streets, though at the same time no hesitation is shown in declaring the supposed economy which gas lighting is showing as compared with electric lighting. On the other hand, our contemporary has recently been indignant at the idea of street lighting by gas being carried on for the sake of advertisement at a figure which is unremunerative.

We are quite prepared to accept the figure of 60 c.p. per cubic foot mentioned by our contemporary for the consumption of the new 3,000 c.p. gas lamps. For 3,940 hours per annum this comes to 197,000 cubic ft. per annum. Having regard to the conditions of the contract, the average candle-power must exceed 3,000, and for that reason we think it permissible to add 10 per cent. to the gas consumption, giving, say, a round figure of 215,000 cubic. ft. Now the Gas Light & Coke Co. have been selling gas for street lighting to the Corporation of London at 2s. 4d., which last October was reduced to 2s. 2d. Presumably this is a price which the Company feel they ought to obtain. Yet if this price were demanded for the new 3,000 c.p. lamps the cost of gas alone would be £23. 6s., whereas the contract price for 15 years is £20. 5s., including maintenance and all other charges as well as gas. Indeed this sum would be wholly accounted for by gas at less than 1s. 11d., and if these other charges merely came to such a modest sum as £5 the price for gas would fall to 1s. 5d. This does not look like running at a profit.

We may look at it in another way. Neglecting tenths of a penny, it may be said, if we accept the figure given by the "Journal of Gas Lighting," that the net cost of gas into the holders (*i.e.* cost of coal and manufacturing charges, less residuals) is 1s. per 1,000 cubic ft. On this basis the gas at cost would amount to £10. 15s. We think, however, that even our contemporary will admit that this is too low a basis on which to supply gas for public lighting. On the other hand, if we go further we find that the cost of gas to the Company, including manufacture (less residuals) and management, but excluding distribution entirely (as this is less for public lighting than for private consumers) is 1s. 4½d. per 1,000 cubic ft. sold. This figure is based on the accounts of the Gas Light & Coke Co. for the six months ended December 31, 1909. The gas at cost would thus amount to £14. 16s. To this must be added a number of charges. There is, for example, the cost of upkeep. In Mr. FRANK SUMNER'S last annual report, which includes figures relating to street lighting in the City of London, the price for upkeep and lighting of a Keith high-pressure inverted gas lamp of 1,500 c.p. is given as £3. 6s. 9d. One might, therefore, anticipate the corresponding charge for a 3,000 c.p. lamp to be somewhere in the neighbourhood of £4. 10s. Then there is the cost of the lamp, which is approximately £20, and which must be wiped off during the period of the contract. The interest and sinking fund for this purpose is not negligible, and doubtless accounts for the difference between the £22 and £20. 5s. quoted for 5 years and 15 years respectively. Further, there is the cost of special mains and compressing plant (which although available for other purposes will, no doubt, be used chiefly for street lighting) and the cost of compressing. Now, when all these items are added together we have at least just cause for suspicion that the margin of profit is negligibly small, if not negative. This remark applies even if gas is taken at a considerably lower price than 1s. 4½d. Unfortunately, figures for these costs are not available, and therefore it is very easy for the supporter of gas to exclaim that the cost of maintenance or some other item for the new lamps is much lower than hitherto, that the price of gas is really much higher than would appear at first sight, or to state that the cost of gas is really so small that there is plenty of room for maintenance charges.

We do not think we need labour the point further. Either the Gas Light & Coke Co. have been making an enormous profit out of gas supplied for street lighting hitherto, or they are supplying on an uncommercial basis for the Westminster contracts. Everything points to the latter. Of course, the Gas Company are quite within their rights in following this policy, and doubtless they feel there are compensating advantages. We cannot complain of this kind of warfare. What we wish to emphasise, however, is that our contemporaries have no right to claim, as a result of these contracts, that street lighting by gas is cheaper than by electricity. Comparisons of this kind should only be made under commercial conditions; otherwise they become more than proverbially odious. We do not, however, impute "dishonesty" to the "Journal of Gas Lighting," and we would merely suggest that it is scarcely necessary for our contemporary to use such a forcible term when criticising our columns.

Meanwhile, events in St. Marylebone, Hampstead, Brighton, Croydon, Exeter, Harrogate, Swansea (to mention a few among many) and on the networks of several railway companies show the other side of the picture. The gas lamps in St. Marylebone are being rapidly replaced by electric lamps, the energy for which is being supplied at a profitable rate, the same as to other consumers of the same class, and the last report of the Council showed that a saving of £1,630 per annum has resulted by so doing up to March 31st. We do not doubt that this saving will be much increased during the present year. Electric street lighting is also advancing rapidly elsewhere, and therefore we see no reason for the electricity supply industry to be cast down by a reverse brought about by the conditions in the Westminster contracts, which were obviously extremely adverse to the electricity supply companies.

VOLTAGE DROP OF TRANSFORMERS HAVING A POOR REGULATION.

BY K. FAYE-HANSEN.

Summary.—The author discusses the testing of transformers for voltage drop, and emphasises the desirability of using Prof. Bragstad's method for this purpose. A number of test results are given for transformers having high reactance.

By the "voltage drop" of a transformer is understood the alteration of the secondary voltage due to the load when the primary voltage remains constant. When we speak simply of voltage drop we mean the algebraic difference between the secondary voltage at no load and at full load, and not the vectorial voltage drop, or, as it is also called, the geometrical voltage drop or the impedance voltage.

The vector diagram, Fig. 1, which is a modification of the well-known Kapp's transformer diagram, will more clearly show the meaning of the expressions used above. In this diagram the following notations are used :—

I_2 the secondary current.
OA equal to V_1, the primary terminal voltage.
OB the secondary terminal voltage at no load.
OC ,, ,, ,, ,, load.
BD the vectorial voltage drop due to the reactance.
DC ,, ,, ,, ,, ,, ohmic resistance.
BC equal to V_2, the total vectorial voltage drop.
OB—OC the algebraic voltage drop.

The algebraic voltage drop is, from the point of view of the voltage delivered to the lamps or motors, the more important, while the banking of transformers is dependent upon the vectorial voltage drop.

Three test methods have been used to determine the voltage drop of transformers :—

1. The secondary voltage is measured at different loads and power factors, while the primary voltage is kept constant.

2. The primary voltage required to force the full load current through the windings when the secondary is short-circuited is measured and also the losses which then take place. By means of the ordinary transformer vector diagram the voltage drop is then calculated for different loads.

3. The magnitude of the vectorial voltage drop is directly measured when two identical transformers are connected in parallel on the primary side, while one of them is loaded and the other unloaded. By means of a wattmeter the phase of the vectorial voltage drop can be determined, and the algebraic voltage drop can then be calculated.

The diagram of connections (Fig. 2) shows, for instance, how the phase difference between the secondary current (measured by the ammeter A) and the vectorial voltage drop (measured with the voltmeter V_2) can be determined by means of a wattmeter, W. This wattmeter reading gives also the copper losses, in a similar way to the normal short-circuit test. If the voltage is zero, the test described above is the same as the ordinary short-circuit test with the only difference that a shunt transformer is used for the measurements of the voltage.

The first method has the disadvantages that the algebraic voltage drop only is measured, and this very inexactly, however carefully the measurements may be made, because it is obtained as a difference between two nearly equal voltages.

The second method is in this respect very much better, but it rests on the assumption that the magnetic conditions for the leakage lines are independent of the voltage, that is, of the induction in the iron of the main magnetic circuit.

The third method is without doubt the best, and is absolutely correct as long as the high harmonics are not sufficiently predominant to make it unallowable to work with the ordinary vector diagrams. This method was, as far as I know, first proposed by Prof. Bragstad in 1901, and it can with small modifications be used for nearly any conditions. With this method, I have previously found that the induction in the iron of the main magnetic circuit has some influence on the voltage drop of transformers. This is due to the fact that the leakage flux has partly to go through the iron carrying the main flux and the magnetic resistance offered to this part of the leakage flux will alter with the induction. For ordinary transformers, however, having less than 4 to 5 per cent. reactance, this influence is too small to be of any practical value.

During the last few years, however, I have designed a number of transformers having a high reactance of 10 to 30 per cent., and have made some similar tests on these. These transformers (being both of the core and of the shell type) were designed to work in conjunction with rotary converters, and were provided with a high reactance to enable a voltage regulation on the direct-current side to be obtained by means of alteration of the excitation of the rotary converter without the use of boosters, &c.

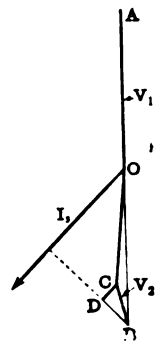

Fig. 1.

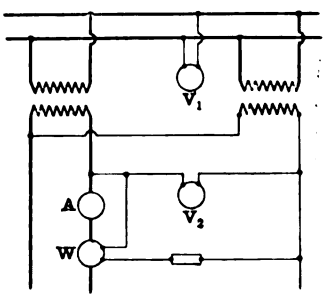

Fig. 2.

The measurements were made in the ordinary transformer test room, and it was not possible to keep the conditions absolutely stable, so that the measurements are not claimed to be very exact, nor had I sufficient time to make them as complete as I should have wished. Notwithstanding this, however, they very clearly show the voltage drop conditions of transformers having a very high reactance.

The tests hereafter described were made with three 100 k.v.a. single-phase transformers of the shell type, having a ratio of turns corresponding to 149 to 6,600 volts, at 50 periods and no load. At this voltage the induction in the iron was about 12,500 lines per square centimetre (special alloyed iron was used), the short-circuit voltage at full load current (15·15 amperes) was, for the transformer on which the measurements were made, 1,584 volts on the high-tension side—that is, 24 per cent.—and the loss measured on the short-circuit test was 1,450 watts. The copper loss calculated from the resistance

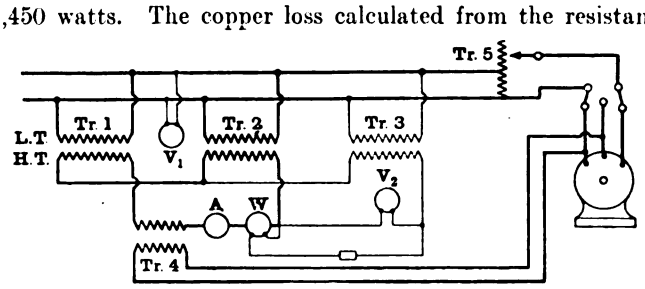

Fig. 3.

measurements was 1,150 watts, while the iron loss during short-circuit was calculated to be about 140 watts, so that the actual eddy losses were about 160 watts—that is, only 12 per cent. of the copper loss. The high reactance in this case was obtained by subdividing the coils once only (HLH) and putting iron laminations between the high-tension and low-tension coils, leaving an air-gap between the main core and these laminations to prevent them becoming saturated.

The connection during the test was as shown in Fig. 3. Tr 2 is the transformer on which the measurements were made, while transformers 1, 2 and 3 are all similar. Different phase angles between current and voltage were obtained by connecting the primary side of the regulating transformer Tr 5 to the different phases of the three-phase generator, while the phase and magnitude of the current through transformers 1 and 2 were kept practically constant. The diagram of connections

Digitized by Google

shows that the regulating transformer Tr 5 was delivering the current and output required for the magnetisation of all three transformers, while the transformer 4 was delivering the current and output required to force the full-load current (15·15 amperes) through the windings of transformers 1 and 2. Tests with six different phase angles were made in the manner described above, giving the results shown in the following table:

L.T. voltage, V_1.	Phase diff. between L.T. voltage and vectorial voltage drop (deg.).	Vectorial voltage drop, V_2.	Wattmeter reading, W.	Phase diff. between H.T current and vectorial voltage drop (P.F.).	Induction inside the L.T. coils calculated from V_1.	Induction inside H.T. coils.
0	0	1,590	1,400	0·058	180	3,000

0	120	1,584	1,440	0·060	180	3,000
25	120	1,584	1,450	0·060	2,100	2,700
149	120	1,550	1,800	0·077	12,500	11,300
0	60	1,580	1,450	0·0605	180	3,000
25	60	1,574	1,440	0·0605	2,100	4,400
73	60	1,562	1,310	0·055	6,100	8,000
127	60	1,530	590	0·025	10,650	12,450
149	60	1,500	380	0·017	12,500	14,200
0	120	1,586	1,460	0·0605	180	3,000
25	120	1,580	1,450	0·0605	2,100	2,700
73	120	1,576	1,450	0·0605	6,100	5,350
127	120	1,560	1,180	0·050	10,650	9,600
149	120	1,504	1,011	0·044	12,500	11,350

The phase difference between the high-tension current A and the vectorial voltage drop V_2 was determined from the equation $P.F. = W/AV_2$. The phase difference between the low-tension voltage V_1 and the vectorial voltage drop V_2 was determined from the connection and checked by means of measurements of the high-tension voltage. The induction within the low-tension coils is calculated from the measured low-tension voltage V_1 taking the ohmic resistance of the low-tension winding into account. The induction within the high-tension coil was determined from the high-tension voltage calculated from the low-tension voltage, the vectorial voltage drop and the phase angles. For the calculation of the induction I assume sine waves and the weight of iron to be 0·275 lb. per cubic inch. The high-tension voltage, which was in several cases checked, proved within the limits of accuracy to be the same as that determined from the measurements of the low-tension voltage and the vectorial voltage drop.

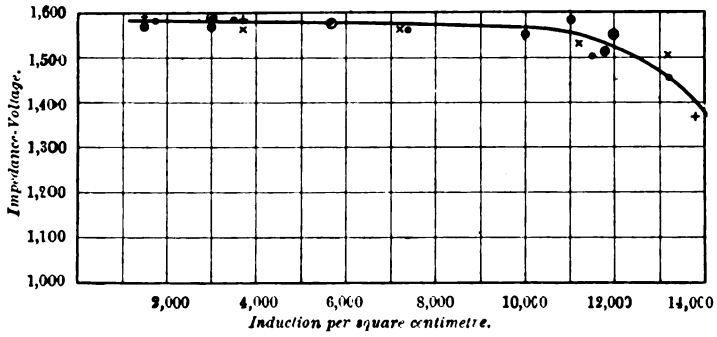

FIG. 4.

The vectorial voltage drop is, in Fig. 4, shown as a function of the average induction within the high-tension and the low-tension coils. Under average induction I understand here the mean between the induction within the high-tension and the low-tension coils as given in the table. It will be seen that for an induction up to 10,000 lines per square centimetre the vectorial voltage drop remains about the same as the short-circuit voltage. At higher inductions, however, the voltage drop is comparatively rapidly reduced. This way of drawing the curve has been chosen because if the vectorial voltage drop were shown as a function of the induction calculated either from the high-tension or the low-tension voltage, or as a function of the highest of these two inductions, the curves would not be so good.

Of further interest is the alteration in the wattmeter reading, and therefore in the phase difference, between the high-tension current and the vectorial voltage drop, dependent upon the induction in the iron and the phase difference between the voltage drop and the no-load voltage. The differences in the wattmeter readings are much too large to correspond to a real difference in losses, especially as this would in some cases mean negative eddy losses; the cause must therefore be that the watts taken from the low-tension side alter with the magnitude and the phase of the leakage field. Unfortunately, the conditions made it impossible to confirm this in my tests. It was, however, ascertained that the current taken for all three transformers on the low-tension side, which must be considered as a sum of the three no-load currents, increased when the current through the windings of transformers 1 and 2 were increased.

I hope that other engineers who have time and opportunity to make similar tests on transformers with a high reactance in a more complete manner will not fail to do so, especially as in ordinary transformers, of course (as well as in three-phase induction motors), the same conditions prevail, but to so small an extent that it is very difficult to obtain good test results.

It would also be of great interest if similar tests were made in three-phase slip-ring motors, as such tests would show how the reactance and the losses due to the load currents alter with the induction in the iron, and also how the "no-load current" and the "no-load losses" are altered with the load currents. In this way it would probably be possible to find an explanation for differences in the results which are obtained with measurement of the no-load and short-circuit currents and of the brake tests on three-phase induction motors.

NINTH ANNUAL CONFERENCE OF THE MUNICIPAL TRAMWAYS ASSOCIATION.

The proceedings of the ninth Annual Conference of the Municipal Tramways Association, which this year is being held at Bradford, were opened on Wednesday by the reading of the Presidential Address by Mr. C. J. Spencer, general manager of the Bradford Corporation Tramways.

There was a good muster of members, including Messrs. A. Baker (Birmingham), J. B. Hamilton (Leeds), J. M. McElroy (Manchester), J. Aldworth (Nottingham), A. L. C. Fell (London) H. E. Blain (West Ham), H. Mozley (Burnley), A. A. Day (Bolton), A. R. Fearnley (Sheffield), J. Dalrymple (Glasgow), and many other engineers and chairmen of tramways committees.

We give below an abstract of Mr. Spencer's address.

PRESIDENTIAL ADDRESS.*

We occasionally hear grave doubt expressed as to the commercial soundness of municipal tramway undertakings. The accounts are freely published in great detail each year, yet our critics say that if our accounts were kept on right lines, and a proper amount put away each year for obsolescence and depreciation, things would appear very different, and sometimes the methods of a well-managed company undertaking are held up as an example of how things ought to be done. From the Board of Trade returns I find that last year company and private tramway concerns put by for depreciation, obsolescence, &c., £251,052 on a capital of £23,888,485, or 1·05 per cent. For the same period municipal tramways put by for the same purpose into sinking fund, reserve and renewals accounts, £1,644,212 on a capital of £47,134,754, or 3½ per cent. Whether municipalities are thereby adequately meeting their obligations is a question which has, on more

* Abstract.

Digitized by Google

than one occasion, been fairly well discussed; but having regard to the above figures, it does not seem that the advocate of private ownership methods has much reason to compare company as against municipal practice with any deprecatory sentiments to the latter. Having regard to the above figures, there seems little reaon to doubt that municipal tramways in the mass are commercially sound.

There does not appear to be any general desire on the part of Corporations to turn their backs on the policy of public ownership and hand over their tramways to private enterprise. The fact of the matter is that experience has proved, in the great majority of cases, that the tramway transit facilities are operated and controlled to the best public advantage by the local authorities in whose area the tramways are located.

Passing from the commercial aspect of the matter, I am not at all sure that citizens have fully realised the immense benefits that a tramway in the hands of a progressive Corporation may have, and probably has, conferred upon the populations of towns, cities, or urban districts. It has not, however, in my judgment, been yet fully utilised for the public good. In the main we, as operators, have devoted all our energies to the carriage of passengers. We have heard on various occasions in the past, for many years, the possibilities of tramways handling local goods traffic, and it is astonishing to find, notwithstanding all that has been said on this subject, that the amount of revenue received from other than passenger receipts is in the ratio of 38 to 1.

One is accustomed to see in our large towns long rows of heavily-laden horse-drawn vehicles moving along the streets at from three to four miles an hour, impeding the fast-moving traffic, and generally reminding one of the dark ages, and yet at the same time we have a metal track capable of carrying vehicles up to any reasonable weight, and an almost unlimited supply of tractive power at our disposal, whereby we could transmit these particular goods at four or five times the speed, with greater safety to the public, and with greater expedition and despatch as compared with present methods.

My own Corporation has this year drawn to itself some amount of attention by asking Parliament to grant further goods-carrying powers to its tramway system. We were not successful in our plea, it being urged against us that so many Corporations already possessed the powers for which we asked, who had not exercised them to any material extent. It was certainly difficult to place evidence before the House of Commons Committee to show any extended business in this direction under the control of municipalities. There may be, and probably are in some cases, very good reasons for not undertaking this class of traffic, but in the majority of cases it seems to me that the matter should receive careful study and consideration. I am pleased to hear that the Corporation of Leeds are going into this matter with their usual thoroughness, and have entered into some large contracts for the carriage of material.

In some towns there is, I believe, a want of cohesion between the streets department and tramways department in cases of snow-storms. Experience seems to have proved that the tramways department has in its hands the most effective instrument for the clearing of the streets of snow, and it certainly only looks to be a matter of organisation for a much better state of affairs to exist in our towns in respect of this item. The practice of some of the Continental cities in this respect is worthy of attention.

Trackless Trolley.—The introduction of this new method of transit into this country will certainly not, as some people seem to think, cause the tramway proper to be an obsolete piece of apparatus, but it will undoubtedly extend the sphere of usefulness of the trolley system. The tramway construction boom has stopped, not because every district that needed better travelling facilities was supplied, but because financial reasons made it impossible to proceed any further into districts where the population was so thin as to be unable to support a capital expenditure of £14,000 to £15,000 per mile of tramway laid.

The petrol-propelled vehicle came along to meet this want, but owing to the operating costs of a petrol motor omnibus service being so high per 'bus-mile, not much advantage, if any, is gained over the ordinary tramway, including its capital charges. The trackless system, however, provides a vehicle as reliable as a tramcar, and at least as cheap to operate, but with a capital expenditure on street work so low that the bugbear of heavy interest and sinking fund charges is practically non-existent. As a result of the report of a deputation to the Continent my Corporation are now the proud possessors of powers for the installation of what they hope will be the first line of trackless trolley in this country.

Other Possible Developments.—Aerial navigation is progressing at a great rate, and whilst I cannot yet even dream of tramcars becoming really trackless, yet not so long ago many wise men proved to their own satisfaction the impossibility of even the present-day achievements of aerial navigation. Coming a little nearer, however, to practical politics, one is reminded of the development of the mono-rail system. The use of the gyroscope opens up possibilities in certain directions that are certainly worthy of the attention of railway and tramway men. Again, the accumulator phase of development is perhaps worthy of more than passing attention.

On the other hand, the traction motor and car equipment is also showing signs of improvement in several directions, but chiefly in the increase of efficiency so far as power consumption is concerned. Reputable makers are now prepared to guarantee 10 to 12 per cent. higher electrical efficiency of equipments than formerly. Truck development is also proceeding, and we have truck makers who tell us that with their particular trucks they will guarantee a saving of 10 to 15 per cent. in electrical energy, and so on. In various directions the tendency is to reduce the power used per ton of material propelled, and I do not think it at all unthinkable that we shall be able to propel our cars in the future with, say, 50 per cent. less energy than at present. If, then, the accumulator of the future is, say, half the weight for the same capacity, there should be interesting possibilities. Lest 50 per cent. saving of power should be thought rather high, I would mention that we are wasting by wearing away brake shoes and tyres about 40 per cent. of the energy we supply to our cars. Regeneration or recuperation is not, in my opinion, quite dead, and the future should see progress in that direction.

In the main, tramways have been very successful in attracting short distance traffic, and undoubtedly the railway companies have felt the pinch of our competition very severely, so far as short distance traffic is concerned. Many railwaymen, however, have realised that tramways are not solely competitors, but act as very valuable feeders for the long-distance traffic. The travelling habit has been considerably developed, and tramway enterprise is largely responsible for it.

Reference was next made by the President to the work of the Association during the past year in connection with, amongst other things, rail corrugation, the price charged for current and assessment; and he finally mentioned that the work immediately in front of the tramway manager seems to be in the close study of those small items of administration that may have played the part up to the present of "unconsidered trifles," such as the wear and tear of brake shoes and tyres and car lubrication, Papers on both of which subjects were being presented at the Conference.

A hearty vote of thanks to the president having been proposed and seconded, Alderman S. Flint (Leicester) read his Paper entitled "The First Decade of Municipal Tramway Working." An abstract of this Paper is given on p. 983 of this issue, and the following is an account of the discussion.

Councillor RODGERS (Newcastle) remarked upon the fact that out of 176 municipal tramways only 84 were worked by municipal bodies, the balance being leased. The rabid municipalist was more harmful to municipal trading than the advocates of private enterprise. He thought that tramcar drivers as compared with mechanics who had served their time, were overpaid. Co-operation was needed among municipalities, and if Manchester and Salford gave the tramway employés the 48-hour week, other bodies should follow suit.

Mr. H. MOZLEY (Burnley) remarked that 'the' examination' of the undertakings in bulk was not strictly fair. He had analysed the Board of Trade returns and found that the whole of the undertakings averaged 7 per cent. on the capital expenditure. The individual returns showed:—

	Per cent.		Per cent.

In steam tramway days the average wage of the drivers was £2. 3s. 10d. per week.

Mr. C. F. SPENCER (Halifax) thought that if the tramways were sold much more money would be realised on them than had been expended. In Denmark tramways were run at a loss, the companies recouping themselves by the increase in land values.

Mr. H. E. BLAIN (West Ham) thought that the tramway manager's views should be given entirely irrespective of party bias. He felt that the reserve funds were quite adequate.

Mr. J. M. MCELROY (Manchester) advocated the extension of the tramways beyond the municipal boundary, in spite of the veto of small outlying townships.

The members then adjourned for luncheon in the Banqueting Hall, at the invitation of the chairman and members of the Bradford Corporation Tramways committee. At the afternoon session of the Conference the discussion on Alderman Flint's Paper was resumed.

Mr. J. DALRYMPLE (Glasgow) put in a special plea for uniformity in matters of tramway management and operation, and hoped that active steps would be taken to obtain this.

Digitized by Google

Councillor TRUMBLE (Croydon) complained of the price paid by most municipal bodies for current for the tramways. At Croydon, though they were unable to get a reduction in price for energy, they had used meters on the cars, and by this simple expedient were saving £6,000 a year.

Mr. J. R. SALTER (South Lancashire Tramways), in a mild criticism of municipal tramways, remarked upon the heavy burdens for street improvements under which the company tramways were being operated. The London United Tramways had expended as much as a million of money in this way, and his own undertaking was saddled to the extent of £100,000; his system served 26 municipal districts, none of which could have had its own tramway. He felt that there was no comparison between the returns upon the capital of company and municipal undertakings. It was a mistake to suppose that where current was purchased from a combined station that the electric light department was making all the money out of the tramways. Further, he could not support the policy of separate stations for lighting or trams, a combined station was the right thing.

Mr. H. E. YERBURY (Sheffield) and Councillor FLINT (Birkenhead) also spoke.

Alderman FLINT, in reply, said that his figures were based on Board of Trade returns, and he regarded them as accurate enough for his purpose. Municipal tramways were not purely financial undertakings, there were other considerations which had first to be taken into account. As to street improvement charges imposed on companies, in many cases these charges were taken over by the municipal authority when it took over the trams from the company.

A hearty vote of thanks was then accorded Alderman Flint for his Paper.

Mr. J. W. Dawson next read a Paper on "The Comparative Durability of Brake Shoes and Tyres." An account of this Paper and of Thursday's proceedings will be given in our next issue.

SMOKE ABATEMENT EXHIBITION AT GLASGOW.

An exhibition of apparatus having "smoke abatement" as its object was formally opened on Friday, September 16th, by Lord Pentland, Secretary of State for Scotland, who was accompanied by the Lord Provost of Glasgow and the Provost of Paisley, and numerous other civic officials, magistrates and councillors. The promoters of the Exhibition are the Corporation of Glasgow; and the collection of exhibits to be seen at the American Skating Rink, Victoria-road, Glasgow, reflects the greatest credit on all concerned, including Councillor D. M. Stevenson, the convenor of the special committee.

On entering the building, the visitor is immediately attracted towards the "Electric House," the exhibit of the Corporation Electricity Department. This is a typical three-room and kitchen house with laundry and bathroom. All the lighting, heating and cooking is carried out by means of some electrical appliance. There is even no necessity to strike a match to light the ubiquitous cigarette, as that is done electrically. The idea has been to demonstrate the use of electricity without going to any extravagance, the lighting being calculated not to exceed 30s. per annum; and efficiently illuminated it is at that by the use of metal filament lamps.

The furnishings and decorations, a feature of which is their light colours, have been lent by Messrs. A. Gardner & Sons, Glasgow. The heating is carried out by means of Murray's new luminous radiators, which radiate the heat on to the floors, &c., the latter acting on the convection principle to heat the rooms. The ventilation is on the Glover-Lyon system, and the small fans have been lent by Messrs. Matthews & Yates and Messrs. Keith, Blackman & Co.

Among the electrical cooking appliances we may mention the General Electric Co.'s oven, the "Phœnix" oven, the Lancashire electric oven (Gray's system) of Messrs. Bertram Thomas, "Silundum" ovens of Messrs. Simplex Conduits, a Bastian oven, and a "Tricity" range of the Berry Construction Co., through their local agents, Messrs. Malcolm & Allan. The latter have a chef in attendance cooking all sorts of edibles.

Electric irons are exhibited by Messrs. Eastman & Warne, the General Electric Co., Messrs. Simplex Conduits, Bastian Co., and the British Thomson-Houston Co. Various kettles, grills, &c., were also on show by the General Electric Co., the B.T.-H. Co., Messrs. Simplex Conduits, and others, whilst in the bath room there is a "Therol" water heater. The "Stannos" and "Simplex" methods of surface wiring are also shown. Laundry demonstrations are being given throughout the day.

With regard to current consumption of the various appliances, some tests were taken which may be of interest. The "Therol" heater for 25 gallons took 200 watts, and fitted with the accelerator (a new attachment to heat 50 gallons) took 1,000 watts. The G.E.C. oven, on which three heats can be obtained, took 3¼ units per hour, the grill 1,400 watts and the hot plate 1,223 watts. The Bertram Thomas oven has two heats, taking 700 watts and 2,500 watts respectively, inclusive of the small pilot light inside, which admits of inspection of the contents of the oven without opening the door. The "Tricity" oven has also two heats, the low requiring 250 watts and the high 900 watts.

In close proximity to this house is an information bureau, with a huge map of the city showing all the street mains, so that intending consumers can be informed "while they wait" the probable costs of anything they should fancy. An artistic 70-page booklet, forming at the same time a compendium, both for power users and householders, and an interesting souvenir, is freely given to all visitors to the house.

Mr. W. W. Lackie, city electrical engineer, Glasgow, and Mr. Davis of his "publicity department" are to be congratulated on the excellent exhibit which has been got together and on the determined effort they have made to increase the consumption of current.

Elsewhere in the show Messrs. Mavor & Coulson are exhibiting 40 H.P. and 70 H.P. totally enclosed motors. The feature of these is the system of ventilation. At the commutator end is a fan, in a separate chamber but driven by the same armature shaft, forcing air through a series of tubes crossing the interior of the motor after the principle of the well-known surface condenser. The cold air is drawn in by the fan and forced out at the pulley end of the tubes perceptibly warmer. It is claimed that these motors will be particularly suitable for fiery mines, flour mills and other places where there is a lot of fine dust, as the outer atmosphere is not allowed to mix with that inside the motor carcase while running. The inspection holes over the commutator have wide, machined metal to metal joints on the principle now advocated for fiery mines. They also exhibit a handy form of vacuum cleaner. Messrs. Drake & Gorham, Spagnoletti & Co., Alston Scott & Co., Watson & Whyte and Potter & Co. have a combined display, the most interesting among numerous appliances being the "Telewriter."

The Beck Flame Lamp Co. are showing 12 of their lamps. By means of a specially made screened box fitted with suitable lenses they also demonstrate the feeding of the arc in one of their lamps, the glare of the arc being reduced so as to allow of its being seen without discomfort.

The Westinghouse Co. and Messrs. Woodward & Co. have a combined display of lamps and well-known gear, while Mr. Alex. Lindsay and the B.T.-H. Co. also combine in a similar manner, making in both cases an effective display, including a country house generating set.

Simplex Conduits, Ltd., exhibit their well-known system of conduits, also metal lamps, surface wiring and other specialities, the show of Holophane shades and globes being very effective and pleasant.

The General Electric Co. exhibit a range of nearly all their productions, the blaze of light impressing the word "Osram" before all others. The first 1,000 c.p. "Osram" to be seen in Glasgow is on this stand. The inverted shade reflectors for use with metal lamps are also shown as well as a 25-lamp country house set. Attention is also drawn to a set of gear consisting of an electric iron which when not in use as an iron can be used to boil a kettle, heat a saucepan or a frying pan, the whole arrangement, including the stand, iron kettle and pans, selling under a sovereign. The new Zig-Zag radiator lamps used in the Murray radiator are also exhibited.

The remainder of the exhibits deal mainly with such apparatus as Anthracite stoves, gas fires, &c., having the object of the exhibition in view.

One interesting fact, however, is apparent to all, namely, that it takes the four 48 in. Blackman electrically-driven fans running continuously to prevent suffocation from gas fumes in the hall.

NEW G.P.O. TELEPHONE EXCHANGE, GLASGOW.

At the invitation of the Postmaster-General of Glasgow and the Peel-Conner Telephone Works a party of technical and daily press men visited Glasgow on Monday, and were conducted round the new P.O. telephone exchange. We have already given a full technical description of this exchange and commented upon its principal electrical and mechanical features.

The company included a number of distinguished engineers, among whom we may mention Sir John Gavey, Mr. A. M. Ogilvie, Mr. H. Hirst, Mr. M. S. Conner, Mr. P. P. Kipping, Mr. C. H. Wordingham and Mr. Chas. Bright.

The visitors were given special facilities for a private and detailed inspection of the exchange during the morning, when

Digitized by Google

they were conducted round by the members of the staff of the engineering department, who courteously explained the principal items of interest. Subsequently a luncheon was given to the party, which by this time had included among its number representatives from the Scottish daily press. During the afternoon an official reception was held by the Postmaster-General at the telephone exchange, and an opportunity was also afforded the company of going over the P.O. trunk telephone exchange, which has been in operation for some years past. The postmaster courteously extended the programme to the telegraph instrument room, which is in the same building as the trunk exchange. This room provided many objects of interest, which the visitors did not fail to appreciate fully.

At the luncheon at the Central Station Hotel the chair was taken by Mr. H. HIRST, who, after the loyal toasts had been honoured, referred briefly to the enterprise of the Post Office engineering department in bringing its Glasgow exchange equipment up to date, and also in placing the contract for the manufacture and installation of the equipment with a British firm. He regarded this step as a healthy sign, and one which indicated a tendency in the direction of encouraging home manufactures, particularly in branches of industry which have previously been regarded as the monopoly of American firms.

Mr. A. M. OGILVIE, replying for the Post Office engineering department, recalled the early telephone experience of the Glasgow Corporation, and also referred to the function which marked the transfer of the Corporation undertaking to the General Post Office. At that particular time the Post Office had pledged itself to the Corporation to do their utmost to improve the telephone facilities of Glasgow, and to bring the entire city installation into line with modern practice. He felt that the new exchange fully testified to the fact that the promise of the department to the Corporation had been well kept.

Bailie DUNLOP, who represented the Corporation of Glasgow in the unavoidable absence of the Lord Provost, spoke in appreciative terms of the new exchange, and also gave it as his opinion that the transfer of the Corporation undertaking to the Post Office had relieved the apprehensions of many of Glasgow's citizens regarding the advisability of the Corporation indulging in telephone enterprise.

Mr. M. S. CONNER, who was enthusiastically received, gave a number of interesting details of the construction of the new exchange, and directed attention to many items of technical and general interest. He commented specially upon the fact that, whereas many telephone manufacturers had sunk a large amount of capital in expensive tools for the production of standard telephone parts, the Peel-Conner Telephone Works had started *de novo*, and were able, therefore, to design afresh a quantity of the special apparatus which was commonly used in telephone work, such as plugs, jacks, keys and relays. He referred particularly to the internal construction of the plugs, which was such that the body was only slightly cut away for attaching the cord. This design eliminated plug breakage due to the weakening of the body near the top of the sleeve. His company has submitted plugs of this kind to extremely severe tests, and they had found that plugs were never broken, but remained serviceable after more than 300,000 insertions in the jacks. As far as the jacks were concerned, springs were employed on each side of the plug, and, further, these springs were placed on edge, so as to avoid the accumulation of dust. Again, there was a positive stop for each spring, which dispensed with adjustments and prevented worn plugs from damaging the jacks by getting on the wrong side of the spring. They were able to say that this design of jack was in a good serviceable condition after more than half a million insertions of the plugs. He wished specially to remark upon the design of the relays. The framework formed no part of the circuit, and the armature springs were not affected by vibration. The armature also formed a magnetic return outside the coil, and during operation shortened the magnetic circuit. By this means the leakage which must exist in single coil relays helped to operate that relay. He stated that this type of relay was 10 per cent. more efficient than those patterns employing a stationary magnetic return, and 20 per cent. more efficient than the type in which the armature formed the return but lengthened the magnetic circuit during operation, being, in fact, attracted away from the coil. He felt confident in stating that the central battery equipment of the new Glasgow telephone exchange was the best in the world, and he thought that, with reasonable care, it would continue to do duty for at least 30 years. He regarded it as an important advance in telephone work that the voltage employed was raised from the formerly accepted standard of 22 volts to 40 volts, and he also considered that, in the provision of the Stone transmission system, using retardation coils and condensers instead of the Hayes system with repeating coils, the articulation was improved, and on short lines anything in the nature of unduly loud speaking was avoided. He considered that the Hayes system was devised for the purpose of facilitating the connection of earth circuit lines with metallic circuit lines; but, as earth circuit lines were now regarded as in the past, he thought that the use of the older Stone arrangement resulted in clearer transmission of speech.

From our inspection of the exchange we cannot speak too highly of the arrangement of the equipment or the manner in which the work has been carried out. The building in West Campbell-street was designed specially for parcel service, but the third floor, upon which the whole of the exchange and its equipment has been installed, affords ideal accommodation. It would be difficult to conceive of a more roomy, better ventilated operating room. Although the work of the exchange girls is not, on the average, of an arduous character, at the same time it must become very tedious at times. For this reason the operators must appreciate the provision of bright and spacious surroundings. We have already commented upon the unique arrangement of the exchange upon a single floor, and we were much impressed with an inspection of the actual equipment. The work which has been put into the cabling, from the point of entry into the building of the lead-covered cables right away through the various racks to the subscribers' and trunk sections, cannot be praised too highly. Praise is particularly due to the engineers for the manner in which the multiple has been carried out.

We can only conclude by expressing our thanks to the management of the Peel-Conner Telephone Works for the opportunity of inspecting the exchange, and we may further express the wish that interested telephone engineers will apply for permission to be shown over the equipment.

THE "SUN" SCREWED TUBE SYSTEM.

The wiring systems that have recently been placed on the market have all been conspicuous on the side of cheapness. Their avowed object has been to overcome the difficulties inseparable from the installation of electric lighting in small houses, if heavy screwed conduit has to be used; and to provide a system which is at once cheap and durable.

There are some, however, who prefer the old systems, and to whom the extra expense is no objection. For these people the Sun Electrical Co. are now catering. In order that the unique benefits of the

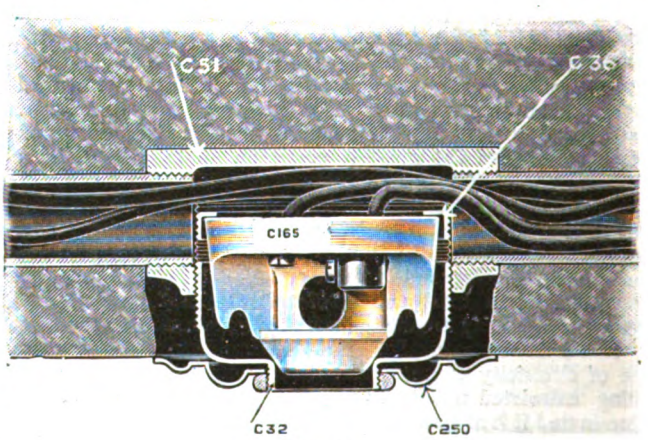

FIG. 1.

"Kalkos" patent box may be still further extended, this piece of apparatus is now being manufactured in malleable iron to take all the standard sizes of screwed steel conduit.

As is well known, the prominent feature of the "Kalkos" box, the new type of which we show in section in Fig. 1, is the adjustment ring. Every contractor is aware of the many difficulties which arise in wiring new buildings in which conduits are buried, when the switches and other fittings have to be fixed. There is always some adjustment to be made in order to bring the switch plate flush with the finished wall, the plaster may not have worked to schedule, with the result that the box is left, perhaps, ½ in. or so deeper than anticipated. In the past this has always been a difficulty hard to overcome. With the patent boxes, it is claimed, it is simplicity itself. The adjustment ring is rotated forwards or backwards as desired, in order to attain the desired level at the front of box. Nearly $\frac{5}{8}$ in. adjustment is thus obtained with any cover. The adjustment obtainable is unlimited, if the correct cover is selected. In flush work a further adjustment is also possible on the switch plate. To fix this the plate is slipped over the projecting male thread on the cover (C32). It automatically adjusts itself to the level of the plaster or wall panel, irrespective of the angle at which the box happens to be fixed, and is securely fastened by means of the milled ring provided. Our illustration shows the component parts of the box in detail with a ceiling rose; C51 being the "Kalkos" iron box, C36 the adjustment ring, C165 the ceiling rose, C32 the cover, and C250 the flush plate. All boxes are

Digitized by Google

of the double compartment type, giving a clear space between the bases of the switches, plugs, or ceiling roses. The bottoms of the boxes can be used as distribution or joint boxes, and thus the number of junction boxes can be reduced to a minimum. By this arrangement joints are accessible at any time by unscrewing the cover and taking out the fittings, the wires behind thus being exposed without disturbing either floors or decorations. A general view of a three-way box is given in Fig. 2, one-way and two-way boxes are also made. An

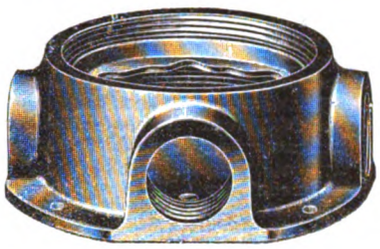

Fig. 2.

important feature of the double compartment type of box is that it gives a clear run through for wires to other points, thus making possible a great saving in material.

Two interesting pieces of apparatus have been introduced in connection with this system. The first of these is the switch shown in Fig. 3. It has been designed to eliminate the difficulties hitherto experienced when using ordinary panel switches in a system which is earthed throughout. It will be noted that in the "Kalkos" switch all current carrying parts are enclosed in a porcelain well. It is, therefore, impossible for any live metal to come into contact with

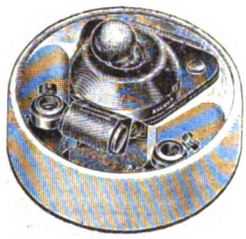

Fig. 3.

Fig. 4.

the switch cover. And when breaking circuit with a switch carrying its full capacity of 5 amperes, there is no risk of an arc being drawn and set up between the terminals and earth. The screws of terminals are so protected by porcelain that even when right out it is claimed they cannot touch the box or cover. Terminals can be tightened up after the switch has been placed in the box, there being channels in the porcelain to admit of the use of a screw-driver. An important feature is that the dolly is effectively earthed to the system only when the cover is screwed into position, but is always automatically earthed as soon as the cover is fixed, there being no connections to make. The

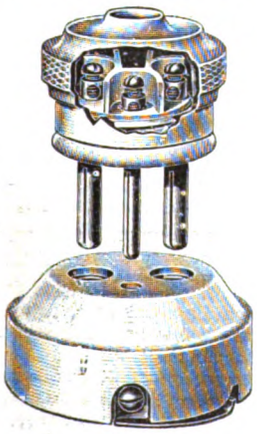

Fig. 5.

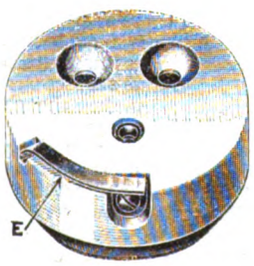

Fig. 6.

switch is both water tight and air tight; this very desirable result is effected by means of the collar, C (see Fig. 4), which keeps the packing, P, tightly pressed round the back of the dolly, D. The entire hole of the cover is coned to take the collar, C, making a gland joint, the whole switch being therefore watertight. The collar and packing is fitted to the switch, there being no loose parts. The base has been designed to check accurately into and fit the adjustment ring, so that no lateral movement can take place. The contact arm of switch is enclosed in marmorite, thus effectively insulating it from the operating mechanism, and at the same time placing an insulated barrier between the two poles of switch when the circuit is broken. The special construction of the contact arm, whereby this moves independently of all other parts of the switch, enables it to roll into position when switching on, the movement being particularly easy. It affords also a very large contact, ensuring as it does the whole of its surface for this work.

Another piece of apparatus is the wall socket and plug, shown in Fig. 5. It has been designed to comply with the requirements of the Factory and Workshop Acts, 1901 and 1907.

The connection to earth is made automatically as soon as the socket is inserted in the box, by means of a spring contact, E (Fig. 6). It is said to be impossible for wiremen to omit to make this connection when fitting. The third pin of the plug is available for the earth wire or sheathing of the flexible and for portable fittings. It is impossible for the "earth" pin to be inserted into a live socket or vice versâ. If this plug is used on three-wire systems, where the tube is used as the neutral, the third pin can be employed to carry current, the pressure between this pin and either of the others being half that of the total voltage of installation.

NEW WATKIN SWITCH.

At the Engineering and Mercantile Exhibition which is at present open at Olympia, the Adams Watkin Co. have an extensive exhibit which demonstrate in a practical manner the application of this well-known switch to the control of lighting, heating and small power circuits. One of the features of the exhibit is a tumbler pattern Watkin switch which has a maximum capacity of 64 watts. This has been brought out to meet the demand for a switch to control one or two metal filament lamps. The switch is very little

Tumbler Pattern Watkin Switch.

larger than the ordinary tumbler switch and is as easily operated. Further, the special carbon resistance element is contained within the circular cover of the switch, so that its external appearance is in no way impaired (*see* illustration). We understand that the Company is experiencing a big demand for this pattern of switch. The exhibit at Olympia is of more than ordinary interest, because the Company has taken special pains to wire up carefully the various sections so that they can explain to the public the value of the switch as a current economiser when used in connection with lamps, fans, irons, electric kettles, radiators, &c. Those of our readers who are unable to visit the Olympia Exhibition, but who are interested in this pattern of switch, can inspect it under actual working conditions at a specially fitted out showroom at the Company's offices in Victoria-street. Here a large office has been fitted up as a modern dining room and practically every application of the Watkin switch can be actually demonstrated.

BOOKS RECEIVED.

(Copies of the undermentioned works can be had from *The Electrician* office, post free, on receipt of published price, adding 3d. for books published under 2s., and 5 per cent, for books published nett. Add 10 per cent. for abroad or for foreign books.)

CONFERENCE OF GOVERNMENT TELEGRAPH AND TELEPHONE ENGINEERS.

A list of the subjects which were discussed at this Conference appeared on page 785 of THE ELECTRICIAN of Feb. 25 last. The Conference was held at Paris from the 4th to the 11th inst. inclusive. The members present were as follows :—

GREAT BRITAIN.—Major J. A. O'Meara, C.M.G., Engineer-in-Chief of the G.P.O.; Messrs. J. A. Stubbs, J. E. Taylor, F. L. Henley, F. Addey, H. R. R. Moore, H. Brown and J. G. Lucas, engineers of the Telegraph Department; and M. Gill, engineer-in-chief of the National Telephone Co.

GERMANY.—Prof. Dr. Strecker, Prof. Dr. Breisig, Dr. Ebeling and Herren Herren, Kuhlmann, Vittichen, Herz, Läschen and Gut.

Bavaria.—M. Bredauer and Dr. Steidle.

Wurtemburg.—Herr Ritter.

FRANCE.—MM. Estaunié, Seligmann-Lui, Frouin, Dennery, Thevenin, Thomas, Tongas, Bouchard, Sins, Lorain, Maureau, Massin, Devaux-Charbonnel, Larose, Pomey and Milon, and J. Carpentier, Meyer-May (Société Industrielle des Telephones), G. Rechniewski (Société Thompson-Houston), Welles (Société Aboilard), Scimia, Viardot and Welles.

AUSTRIA.—Herren Arthur Linninger, Ernst Petritsch, and François Stecher de Sebenitz.

HUNGARY.—MM. André Kolossvary, Jos. Hollos, Samuel Haltenberger, Béla Gáti, Béla Julcher, Ennó Berdenich, Augustin Major, Miksa Dénes, and Eugene Fritz.

BOSNIA-HERZEGOVINA.—Col. H. Goiginger and M. Ad. Daninger.

BULGARIA.—M. Vassil Chlébaroff.

ITALY.—Prof. Giovanni di Pirro and Signori Enrico Mirabelli and Salvatore Montinari.

HOLLAND.—MM. A. E. R. Collette and V. C. Proper.

DENMARK.—M. W. G. Thomsen.

BELGIUM.—MM. Roosen and Colson.

RUSSIA.—MM. Evangoulow, Louis Tolloczko, Centkowski and Roubanovitch.

SERVIA.—MM. Milan Georgevitch, D. R. Dimitrievitch and Miloutin Vouiadinovitch.

ROUMANIA.—MM. Vidic and Jancolesco.

NORWAY.—MM. Sivert Rasmussen Abild and Léonhard Iversen.

SWEDEN.—MM. Landstrom, Pleijel, Carl Egner, Gunnar Hólmström and Kinmanson.

TURKEY.—MM. Mehmed Emin-Bin Ali and Mehmed Sabri Effendi.

UNITED STATES.—Messrs. C. E. Scribner, and John J. Carty (American Telegraph and Telephone Co.)

BUREAU INTERNATIONAL DE L'UNION TELEGRAPHIQUE.—M. Crescitz.

LEGAL INTELLIGENCE.

Torquay Tramways Arbitration.

On Friday last week Mr. Archibald Read resumed the arbitration between the Torquay Tramways Co. and Torquay Corporation as to whether the Corporation are unreasonably withholding their consent to the adoption of the overhead system of traction on a length of tramway in substitution for the present Dolter system.

Mr. STANLEY CLEGG, city electrical and tramway engineer, Lincoln, said five years ago his Corporation adopted the G.B. system. A guarantee was given that the current consumption should not exceed 1·337 units per car-mile, and that not more than 18 studs per annum should be left alive and undetected by the car. If undetected by the car they could not be left in such a state as to be dangerous. The earthing strip carried away any surface leakage to the rails, so that it was impossible for a stud to charge itself up and cause damage. The current consumed was 1·219 units per car-mile in the first year and 1·075 in the year ended March last. The current necessary to excite the magnets was guaranteed at 580 watts. It had been reduced to 260 watts. In the whole five years no stud had been left alive and undetected, and there had been no accident either to persons or to animals. Car-miles run last year were over 156,000, working expenses were ½d. per car-mile below those of all other municipal electric tramways. The G.B. system had some advantages over the overhead system as regards quiet running, safety and sightliness. They had had three bad winters which brought down telegraph wires in the neighbourhood. Their line was flat and straight. They had an increasing number of live studs, but it had not exceeded the guarantee. Last year the guarantee as to maintenance cost was exceeded, but the average for the five years had not exceeded the guarantee.

Mr. W. M. MORDEY said he had studied all the systems of surface contact traction. His firm advised the original Dolter Co. n July last he was called in by Torquay Corporation to report as to the system. He had had nothing to do with the Dolter Co.'s work for eight years. He reported that the system could be improved so as to be satisfactory and also that other surface contact systems could be used satisfactorily. He found the system was working very well, although the line had not been kept up so as to satisfy an engineer. The thing was, to the public, a complete success; but to the company it was not. He felt that it could be saved comparatively easily. He examined very few studs under the road. He then explained improvements proposed by Mr. Mitchell and approved by himself. Most of the troubles came about through the inner vessel, and Mr. Mitchell proposed to do away with it. Mr. Mitchell had also introduced a more powerful armature and a longer lever, which would enable a better contact to be made by the contact bases beneath the stud with the same excitation of the skate, even with the skate quite clear of the road. The longer lever would also make a clearer break. The single pot arrangement would permit of the whole apparatus being easily withdrawn and examined. The interior of the pot would be filled up with oil and be open at the top, and, not being gas-tight, the danger of explosions would be minimised. He produced a sample of oil such as is used on the Hastings tramways, and which he said was thin enough to allow the lever to work and yet of sufficient specific gravity to keep out sea water. It was 8·8 per cent. heavier than fresh and 6 per cent. heavier than sea water. He exhibited a model which showed that the proposed new armature for making the contact under the stud would make a better contact with the skate 3 in. above the stud than the old apparatus would make with the skate touching the stud. The inner vessel becoming loose, the contact bases might not remain opposite one another, and that was likely to lead to arcing and increase the carbonisation of the oil. Another trouble with the two pots was that the thick oil from the outer pot got into the inner pot, but with the single pot only the thin oil was used. He did not think water would creep down the inside of the single pot. He thought Mr. Mitchell had now, at one blow, solved a great many of the difficulties. The total current loss, including all losses between the station and the car, and also on the return, was 11·9 per cent. He would expect the current used on the overhead system to be from 6 to 7 per cent. less. There was not much cause to complain of the cost of the energy at Torquay. On some of the lines he should say that more than half of the studs were out of order when he inspected the tramways, and the system had not had a fair chance. At Torquay (one of the hilliest tramway systems in the country) the current consumed was 2·24 units per car-mile, and at Huddersfield, which was also hilly, the current used on the overhead system was 2·25 units. At Lincoln the current used on the G.B. system was only 1·1 units, but the line there was flat. Even after the Board of Trade's final intimation that they would not renew their order permitting the working of the Dolter system at Torquay after the date previously fixed, he would still, if he had been the engineer of the system, have spent more money on improvements, as he believed that the Board of Trade were a reasonable body, and that they would have withdrawn their decision if the line had been made to work reasonably well. He thought the contact parts would make a better break in oil which was partly carbonised if the magnetism were great than if it were small, because with a good contact there was less tendency to heating. Although he had not made any tests on the tramways of the oil he had produced, he had had experience of the working of switches and other electrical apparatus in oil, and upon that he based his opinion that the levers and contacts in the pots would work in the oil submitted. He did not know that the creeping action of water was greater along porcelain than on other substances. He thought it would be greater on less highly glazed surfaces. This, and the fact that Mr. Holliday had said that on scraping the outer surface of the inner pots, which had become conductors owing to the carbonisation of the oil, they had again become non-conductors, led to the conclusion that the water crept down on the outer surface of the inner pot, rather than the inner surface of the outer pot.

Col. SPRAGGE (mayor of Torquay) said the Torbay-road was regarded as one of the most beautiful marine parades in the kingdom, and they were averse to anything that would interfere with its beauty. The vote in the Council was almost unanimous against permitting overhead tramways.

Mr. VESEY KNOX said the Council were not only considering the beauty of the town, but their action was an attempt to squeeze the company. He asked the arbitrator to order the Corporation to produce the Tramway committee's report of May 14.

The ARBITRATOR said he would consider the point.

Mr. F. S. HEX (town clerk of Torquay) said the Corporation thought that with proper attention the Dolter system could be made to work satisfactorily, and they continually communicated with the company upon matters that they thought would result in the improvement that the Board of Trade said must take place. If it had not been for the assurances the Corporation had received from the company as to the continuance of the surface-contact system they would not have supported the 1909 bill authorising the Paignton extension.

Mr. VESEY KNOX said the company were authorised by Parliament to work the tramways, and the Corporation were not justified in exercising their veto to prevent them from being worked at all. Finding they could squeeze nothing more out of the company the Corporation said, "Let them stew in their own juice." He submitted that the authority's action was cruel and unreasonable.

The hearing was concluded on Saturday, and the arbitrator reserved his award.

Mining Regulations.

On Tuesday the Sheriff of Linlithgow heard a charge against James Jones, jun., and Scott Lees (agent and manager respectively of the Dalmeny Shale Mine of the Dalmeny Oil Co.) for having (1) on June 20,

Digitized by Google

1910, failed to maintain the electrical apparatus in the Douglas Dook part of the mine in such a condition as to reduce the danger through accidental shock to the minimum, in respect that the casing of the motor working the pump in the dook was alive; (2) for having failed to protect the terminals on the motor and controller either with insulating covers or metal covers connected to earth, notwithstanding that protection in one or other of these ways was practicable; (3) for failing to maintain the conductors to the motor completely insulated from earth; (4) for failing to make the roof and sides of the travelling road to the motor secure, and allowing an electrician at the mine, who was not a person appointed for exploring or repairing, to travel on the road on the date in question; (5) for failing to have the terminals and commutator contacts, which were dangerous and exposed parts of the motor, securely fenced; and (6) for allowing on the dates mentioned the wires lighting the circuit at the east side haulage motor to rest on an iron girder, and, further, in one place allowing a staple to be used as a fastener, all in contravention of the Coal Mines Regulation Act and the Special Rules of the Home Office as to the use of Electricity in Mines.

Mr. JAMES KIDD, solicitor, who appeared for respondents, took exception to the relevancy of the complaint in respect that the execution of the electrical rules being in the hands of an electrician, it must be specified wherein the manager or agent had done or omitted to do something in the way of supervision which involved them in the offences charged, and that in any case the manager, who was technically qualified, and technically guaranteed by his certificate, was responsible primarily in a question between him and the agent, the latter of whom did not require any technical qualification, and therefore in such a question it must be set forth clearly how the agent was involved in responsibilities. He submitted that the manager and agent appearing on the complaint as framed were mutually exclusive of each other, and if that point were sustained the whole complaint must drop.

Sheriff MACLEOD indicated that with regard to the general objection based on the relative positions of the agent and the manager he confessed that he would have preferred to see them treated separately, as having been guilty of separate offences. However, he thought that that might be inferred from the reference to the different rules, and if that might be so he was not inclined at that point to sustain the objection and dismiss the case. The other objections he dismissed, with the exception of an objection taken to the libel in so far as it charged the respondents with allowing a man to walk in an insecure road. He agreed with the construction put upon the section by the accused's agent as being the correct one, and he held the complaint in that respect irrelevant.

Respondents tendered a plea of not guilty, and proof was fixed.

Workmen's Compensation.

At Birmingham County Court on Monday Judge AMPHLETT, K.C., heard an application by the British Thomson-Houston Co. for the review of a memorandum of agreement (filed Nov., 1909) for the payment of £1 a week to George Mackenzie, an electrician, of Handsworth.

Mr. CAVE (for applicants) said respondent was employed by them in Dec., 1905. On the 24th of that month he met with an accident through the bursting of a naphtha can, which inflicted burns on his body. He was unable to work for some time, and was allowed £1 a week down to May 2, 1908. On July 28, 1908, respondent re-entered their employment, and did the same work at the same rate of wages. He remained until Dec., 1908, when the job came to an end. There was a question whether applicants had entered into an agreement which settled the whole case. The agreement, by which he accepted £12, was signed by respondent. Apparently respondent's contention was that, though he signed the agreement, he did not read it, and, therefore, was not bound by it. Mr. Cave read letters which had passed between the parties, and said that at a previous hearing Judge Ruegg decided that respondent did not think he was settling his claim when he signed the agreement, but, because of his carelessness, deprived him of his costs. That decision came before the Divisional Court, when it was decided that the matter should be referred back to the County Court, with liberty to set up the agreement as the reason for demanding the termination of compensation.

Dr. LEONARD GAMGEE said he considered respondent was now able to do the work of an electrical engineer. There was a slight loss of agility, but he did not think there would be any loss in ability. He did not consider respondent was quite so capable of doing constructional work which necessitated the use of scaffolding.

Mr. ARTHUR TURNER, in the employ of the B.T.-H. Co., said he handed over £12 to respondent, and had no doubt he read the agreement before signing it. The work on which respondent was engaged from July to Dec., 1908, was precisely the same as that he had done up to the time of the accident.

Respondent stated that since the accident he had not been able to earn anything at his own trade. He had opened a little newspaper shop, but had made an average of only 6s. 7d. a week. A large part of the exterior of one of his legs was practically insensible to pain, and the sole of the foot was practically dead. He was claiming £12 arrears, and he understood it was a receipt for that sum, and, therefore, he did not read it.

Dr. E. RUSSELL HENNESSEY said he had had respondent under his care. In July, 1903, when respondent was asked to go back to work, witness did not consider him fit to undertake the duties of an electrical engineer as he understood them. He still held that opinion. There was a contraction of the left leg, which was about ¾ in. shorter than the right.

The hearing was adjourned until to-day.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

A leading draughtsman is required for designs of starters, rheostats, iron-clad switchgear, &c. See an advertisement.

A draughtsman is wanted for a.c. and d.c. generators and motors. See an advertisement.

Test-room assistants are required, used to calibrating m.c. and e.m. instruments. See an advertisement.

Applications are invited for the position of resident engineer for one of the electricity works under the control of the County Borough of Stoke-on-Trent. Applicants must have a thorough mechanical training and experience in a three-wire d.c. station. Salary £180. Forms of application from the chief electrical engineer, Mr. C. H. Yeaman. Applications to the town clerk, Mr. E. B. Sharpley, by 26th inst.

An electrical engineer is required to take charge of the Cambuslang electricity and refuse destructor works of Lanark County Council. Commencing salary £160. Applications by Sept. 26.

Mr. Ingram has been promoted to the position of second engineer at Bermondsey (London) electricity works, in place of Mr. Cragg resigned, at £120, rising by annual increments of £10, to £140 per annum. It was recommended that Mr. Oake, jun., engineer in charge and switchboard attendant, should be appointed third engineer, at £110, rising to £130 a year, but the Council rejected the recommendation and decided to advertise for applicants for the position.

Mr. T. J. Considine has been appointed charge engineer at Taunton electricity works, in place of Mr. E. B. Barton resigned.

Mr. W. A. Scott, assistant works manager, has been promoted to the position of works manager to Bruce Peebles & Co., in succession to Mr. W. V. Waite, resigned.

EDUCATIONAL NOTICES.

University of London, University College.—The session in the faculty of engineering begins on Oct. 3. The provost and the dean will attend on Monday and Tuesday (Oct. 3 and 4) from 10 a.m. to 1 p.m for the purpose of interviewing students and advising them as to their courses.

In addition to the regular undergraduate courses, the following post-graduate courses (which will include lectures, drawing office work and demonstrations) will be given during the coming term: Electrical design, by H. M. Hobart, B.Sc., M.Inst.C.E., M.I.E.E., on Mondays from 5 to 7, beginning Oct. 10. Steam turbines (supplementary to course in session 1909-10), by Mr. E. G. Izod, on Fridays at 5:30, beginning Oct. 21. Railway engineering, by H. Deans, M.A. (Cantab.), M.Inst.C.E., on Mondays and Thursdays at 5, beginning Oct. 6. Photographic surveying, by M. T. Ormsby, M.Inst.C.E.I., on Fridays at 4, beginning Oct. 14.

University of London, Goldsmiths' College.—The new session commences on Monday, Sept. 26, and the enrolment of students commenced on 19th inst. Complete courses of instruction are provided in mechanical, electrical and constructional engineering, telephony, fitting and machine pattern making and smithing, land surveying, &c. Students are prepared for the London University degree of B.Sc. in engineering, for the examinations of the Institution of Civil Engineers, Board of Education and City and Guilds of London Institute and for the National and Whitworth scholarships. There are reduced fees to course students if paid by Sept. 23. Particulars of fees, &c., from the Warden, Goldsmiths' College, New Cross, S.E.

University of Edinburgh.—The next session opens on Oct. 4. In the engineering department of the University complete courses of instruction are provided in civil, mechanical and electrical engineering, qualifying for the degree of B.Sc. in Engineering, and extending over a period of three years. Particulars of entrance examination scholarships, fees, &c., can be obtained from the Matriculation Office of the University.

University of Bristol.—At this university complete courses of instruction in electrical, mechanical and civil engineering are given, and also instruction in the evening classes. The 1910-11 session in the faculties of arts, science and medicine will commence on Oct. 3, and in the faculty of engineering began on Sept. 13. Particulars and prospectuses from the registrar, Mr. James Rafter.

Armstrong College, Newcastle-on-Tyne.—The next session commences on Sept. 26. There are full courses of instruction in mechanical, marine, civil and electrical engineering, naval architecture, mining, metallurgy, agriculture, pure science, arts and letters. Particulars from the secretary, Mr. F. H. Pruen, M.A., Armstrong College, Newcastle-on-Tyne.

Digitized by Google

Battersea Polytechnic (London, S.W.).—The day courses at this Polytechnic prepare for the B.Sc. degree (in engineering) of the University of London, and for the Polytechnic diploma in mechanical, electrical, civil and constructional engineering. The day courses commenced on 22nd inst. and the evening courses start on 26th inst. Prospectuses from the Secretary.

Borough Polytechnic Institute.—The new session begins on 26th inst. There is a four years' course of instruction in electrical engineering, and in electric wiring there is a three years' course. There are day and evening classes. Further particulars and detailed syllabus are given in the prospectus, which can be obtained from the Principal, Mr. C. T. Millis.

The prospectus for the 1910-11 session, which commences on the 26th inst., gives particulars of the varied work carried on in the Institute. Amongst the alterations are the re-arrangement of the electric wiring courses, and there are some new classes in mechanical engineering. There has been an extension and development of the work in nearly all departments. Copies may be obtained from the Principal.

Northampton Polytechnic Institute (London).—Full day courses in the theory and practice of mechanical and electrical engineering and electro-chemistry will commence on Monday, Oct. 3.

The courses in mechanical engineering include specialisation in automobile and aeronautical engineering, and those in electrical engineering include specialisation in radio-telegraphy. The entrance examination takes place on Sept. 28 and 29. Three entrance scholarships of the value of £52 each will be offered for competition at the entrance examination. The courses include periods spent in commercial workshops and extend over four years. They also prepare for the degree of B.Sc. in engineering at the University of London. There are full and part time courses in all branches of technical optics. Particulars as to fees, &c., can be obtained at the Institute, Clerkenwell, E.C., or on application to the principal, Dr. R. Mullineux Walmsley.

South-Western Polytechnic Institute (London, S.W.)—At this Institute a complete three years' course in electrical engineering is held during the day, and a four years' course in the evening. Courses of lectures and practical work are given in a number of subjects, including elementary, intermediate and advanced electrical engineering, electrical design, instruments and lamps, alternating and polyphase currents, wiring and fitting, and the calculus for engineers. Particulars from the Secretary, Manresa-road, Chelsea, S.W.

The prospectus of the day and evening courses which are provided at this Institute (for men and women) has been issued.

The evening classes commence on 26th inst. and the day college opens on Oct. 3. The institute is provided with well-equipped electrical, mechanical and physical, chemical and metallurgical laboratories, and wood and metal workshops, &c., with a well-qualified staff of lecturers, demonstrators and instructors. The full course of instruction in electrical engineering extends over three years, and affords a theoretical and practical training for those who intend to take up electrical engineering as a profession. The courses of instruction provided at the polytechnic also prepare for the degrees of the University of London. Further particulars may be obtained at the polytechnic, or Manresa-road, Chelsea, London, S.W.

Sir John Cass Technical Institute.—A course of evening lectures and practical work on "Fuel" will be given at this institute during the session 1910-11, including one on "Liquid, Gaseous and Solid Fuel," by Mr. J. S. Brame, on Monday evenings, 7–8 p.m., commencing Oct. 17; one on "Fuel Analysis" (and course of laboratory work), by Mr. C. O. Bannister, during the summer term on Monday evenings, 7–10 p.m., commencing April 24; and a course of laboratory work on "Gas Analysis" in the summer term, by Mr. Chas. A. Keane, D.Sc., Ph.D., F.I.C., on Wednesday evenings, 7–10 p.m., commencing April 26. The courses of instruction are arranged to meet the requirements of those engaged in chemical and engineering works, or who are concerned with the use of fuel for motive power. Detailed syllabuses of the courses may be obtained at the offices of the institute, Jewry-street, Aldgate, London, E.C., or by letter to the Principal.

Electrical Standardising, Testing and Training Institution.—This institution has two departments—viz., a training department and a standardising and testing department. We have received the electrical engineering syllabus, which gives particulars of the courses of instruction, fees, exhibitions, &c.

The training department provides students with a thorough training (theoretical and practical) in electrical engineering. The full course occupies four years, arranged so as to combine theoretical training with practical experience. The first year is spent at Faraday House, the second at engine manufacturer's, the third at Faraday House, and the fourth at an electrical manufacturer's or power house. The institution has a permanent staff of well-qualified teachers, and there are also special lecturers on certain electrical engineering subjects. In order to keep the instruction abreast of modern developments, frequent lectures are given during the advanced year by engineers in practice upon the branches of electrical engineering in which they have specialised. The special lecturers include Mr. W. R. Cooper, M.A., B.Sc., Mr. W. H. Eccles, D.Sc., Mr. H. M. Hobart, B.Sc., Mr. J. Rennie and Mr. R. J. Wallis-Jones. Further particulars from the Secretary, Faraday House, Southampton-row, London, W.C.

Bradford Technical College.—The calendar of the day section for the 29th session (1910-11) has been issued, and contains particulars of the courses of instruction in engineering, chemistry and dyeing, &c.

Rutherford College (Newcastle-on-Tyne).—Yesterday (Thursday) Prof. M. Sadler inaugurated the new wing extension for technical instruction which has been erected at this college.

BRITISH NOTES.

Assessment of Machinery.—The Machinery Users' Association write reminding our readers who are manufacturers and machinery users in the London area, that the quinquennial re-valuation of London is not yet completed notwithstanding that the lists were sent in as long ago as June 1. The Association notify that a great number of assessments will be altered and increased when the valuation lists are readjusted, and there will then only remain seven days before they will be irrevocably closed for the next five years. Persons who may not be members of the Association are informed that information for their guidance will be provided if they will communicate with the secretary at 22-23, Laurence Pountney-lane, London, E.C.

Belfast.—The arc lighting of High-street and Castle-place was inaugurated on 15th inst. "Sunræ" flame arcs of 2,000 c.p. each are used.

Bermondsey (London).—A special meeting of the Council will be held on Oct. 18 to consider the question of applying for a provisional electric lighting order for the district of the late St. Olave Board of Works. Two companies already supply electricity in the district.

Bishop's Stortford.—The Board of Trade have been inquiring into the steps taken to carry out the provisions of the electric lighting order, 1905, and the Lighting committee have been instructed to report upon the matter.

Cable Rates within the Empire.—At a conference of the Institute of Journalists last week the subject of an electrical girdle of cheap cables was introduced by Mr. R. McMillan, of Sydney, N.S.W., in its relation to cable rates within the Empire.

Mr. McMillan moved: "That the time has arrived for binding the Empire together with an electrical girdle of cheap cables." He asked that some of the money expended on ironclads should be spared to bring the oversea dominions into closer communication with the Motherland. What was wanted was a Government cable across the Atlantic.

Mr. Henniker Heaton, M.P., of course supported the motion, using the familiar formula "that the cables of the world were now in the hands of monopolists or cable rings." He contended that these undertakings should be bought out at the market price of the day by the Governments of the civilised world. [He did not say whether he had gone into the figures of the proposal.] This great Empire (he continued) would never be perfect until they made communication with the Fijis and New Zealand as cheap as it was to-day with Ireland. It only meant the expenditure of a few thousand tons of copper wire. He did not wish to do injustice to anyone, but if by some miracle the whole cables of the world were melted, or if they were destroyed to-morrow by some great earthquake, they could be reconstructed at one-third the original cost. It was advisable at all costs to put an immediate end to all cable monopolies. The excuse that merchants had so built up their codes that they were able to send even to Australia at the rate of 1d. per word was no reason why the masses of the people who could not arrange codes or anything of the kind should be debarred from being able to communicate by telegraph. There were about 16 lines to America—13 from this country—and he had published the statement, and it had not been contradicted, that 10 of these lines were kept idle by the ring.

Mr. D. H. Maling, of Melbourne, hoped that the extension of cheaper cables would not be confined to Australia, and disclaimed any idea to press forward any scheme which would add to the taxation of this country. Australia should itself pay for every facility obtained.

The President (the Hon. H. Lawson) gratefully acknowledged the manner the Pacific Cable Board and the Eastern Telegraph Co. had offered the Cable committee and the Imperial Press Conference reductions in rates for Press messages. These reductions would be extended under guarantee of a larger amount of telegraphic business. With regard to the Atlantic cables, he had reason to know that last year the Government of Canada was moving in that direction, and he thought the mission of the Postmaster-General of Canada to this country at the present time would also have some bearing upon this question. The whole problem had to be dealt with in a broad and statesmanlike way. There was the alternative of wireless telegraphy, but while wireless telegraphy did not fulfil all their requirements they were still dependent upon cable communications.

Mr. McMillan's resolution was then adopted.

Croydon.—The Tramways committee have been authorised to prepare specifications, &c., for new tramcars.

Dublin.—The Lighting committee have been instructed to provide in their estimate for 1911-12 for the electric lighting of the New Kilmainham Ward.

Digitized by Google

Eastbourne.—From the electricity supply department we have received the revised scale of charges which comes into force on Oct. 1.

Lighting supply will be given at 5½d. to 5d. per unit, outside arc lamps or incandescent lanterns from 4½d. to 4d. per unit, heating and cooking from 2½d. to 1½d. per unit, power (as heretofore) on sliding scale, 2½d. to 1d. per unit.

Edinburgh.—On Tuesday the City Council were recommended by the Electric Lighting committee to apply the surplus on the past year's working of the electricity undertaking (£7,300) towards the reduction of the capital moneys borrowed.

The Lord Provost said it was most unusual to apply to the engineers for advice. He thought as that was an important matter, and a new departure, that they ought to have a report from the Town Clerk and the Chamberlain upon it.

After a brief discussion, the suggestion of the Lord Provost was agreed to.

The Electric Lighting committee are considering the question of extending the mains to Barnton district.

Electric Power in Bootmaking.—Manchester Guardians have decided to instal electric power at the bootmaking department of the industrial schools.

Engineers' Wages.—A conference took place on Monday at Newcastle-on-Tyne between members of the Federation of Engineering Employers and representatives of the Amalgamated Society of Engineers, the Steam Engine Makers' Society, the United Machine Workers' Association, the Electrical Machine Workers, and the Smiths and Strikers' Society, with respect to an application by the men for an advance in wages of 10 per cent. on piece rates and 2s. per week on time rates.

The last change of wages was a reduction in 1908. Mr. Summers Hunter presided, and about 15,000 men were represented. For the men the advance was demanded on the ground of improved trade, and the reduction of their unemployed from 2,000 last year to 650 in August. The employers contended that trade did not warrant the advance, and stated that fewer men were employed in the federated shops than in 1906. The advance was finally refused after a two hours' conference, but the employers intimated that if the men thought it desirable they would be willing to have another conference later.

Exhibitions.—The ninth international motor exhibition will take place at Olympia (London, W.) from Nov. 4 to 12. Further information from the Exhibition Manager, Society of Motor Manufacturers & Traders, Maxwell House, Arundel-street, London, W.C.

An international exhibition of iron and metal wares and machinery will be held at Budapest in May next. Particulars from the Ausstellungs bureau, Gyarutcza 38, Budapest. Applications for space by Nov. 30.

Gateshead.—The extensions of the tramway system were officially inspected yesterday (Thursday).

Grimsby.—At the meeting of the Lighting committee on Monday the chief electrical engineer (Mr. W. A. Vignoles) reported the completion of the installation of Jandus enclosed arc lamps in place of the old street arc lamps. The lamps were working satisfactorily, and giving much less trouble than the old lamps. It was decided to place a contract for the supply of metal filament lamps for street lighting at £15 per gross. 20 new consumers have been connected during the past month.

Hammersmith (London).—The Council recently approved a proposal to permit the New Olympia Co. to generate current at Olympia for the electrical exhibition to be held in September, 1911, the company to pay to the Council a royalty of ¾d. per unit generated. As the company now desire the Council to fix a lump sum the Electricity committee recommend that an alternative charge of £1 per kilowatt installed during the period of the exhibition be offered.

Harrogate.—The suggestions of the electrical engineer (Mr. G. Wilkinson) as to the heating of sulphur water by electricity are to be embodied in a letter and submitted to the Wells and Bath committee.

Application is to be made to the Board of Trade for consent to supply electric current to certain premises outside the present limits of supply.

Ince.—Wigan Corporation have received sanction to borrow money for extending the electric lighting mains to the Ince district.

Keighley.—On Tuesday the Tramways committee recommended that a bill be promoted to authorise the equipment of a trackless trolley system connecting the borough with Crosshills and Sutton Mill with Stockbridge and Nab Lane, with Oxenhope, and penetrating the Fell Lane district.

The chairman of the committee (Mr. J. Mitchell), who moved the adoption of the report, pointed out that from April 1 to Sept. 15 the motor 'buses had earned £2,507, or 11·78d. per mile, on a run of 51,000 car-miles. The cost had been about 9d. per car-mile, and he argued that they might save 3d. per mile under the new system. He was perfectly satisfied that it would pay the Corporation to go to Parliament for those powers alone. The system under consideration would cover a distance of about 23 miles.

Mr. A. Smith seconded, and gave figures as to the improvement in the traffic and profits of the existing Keighley tramway system, which had managed to get rid of the debt inherited from the old horse-car tramway. The Keighley lines had cost £4,480 per mile, while the trackless system could be put down at £1,200 to £1,500 per mile. He thought the cost of a bill would be recovered in a single year.

The recommendation was adopted by 16 votes to 5.

Library Lighting.—Deptford (London) Public Libraries committee report that, having obtained advantageous terms from the London Electric Supply Corpn., they have decided to adopt electric lighting in the New Cross branch library. The committee add, "This form of illumination is the most suitable for library buildings."

L.C.C. Tramways.—It is announced that necessitous blind persons, properly authenticated and accompanied by a guide, will be carried free on the Council's tramcars, but the guide will be charged the usual fare. Authorities of institutions at which such blind persons live or are employed should apply for free passes to the Chief Officer of Tramways, 62, Finsbury-pavement, E.C.

Manchester.—In reference to the recent sanction to a loan of £40,000 for extensions of the electricity department, the L.G. Board have informed the local Ratepayers' Association that the question of holding a local inquiry into the application was a matter entirely within the Board's discretion.

Of the amount sanctioned, £30,000 was required in respect of motors, switch-gear and transformers, and was based on average expenditure of the Council for those purposes, while the balance (£10,000) was for substation plant required to cope with the anticipated demand for lighting, power and traction during the forthcoming winter. The Board have received a further application by the Council for sanction to a loan of £30,000 for a turbo-alternator at the Stuart-street station, and have decided to hold a local inquiry into this application.

The Ratepayers' Association have also challenged the right of the Tramways committee to manufacture electric tramcars. The Town Clerk claims that the power to manufacture is conferred by sec. 8 of the 1899 and sec. 32 of the 1900 Corporation Tramway Acts; but the association claims that these sections only give authority to provide cars. The matter is to be considered by the committee.

Market Lighting.—Swansea Market committee, who are reorganising the local market, are considering the question of re-arranging and improving the electric lighting installation.

Melrose (N.B.).—The Electric Supply Corpn. intend to lay electric lighting mains across the Tweed to Gattonside.

Morecambe.—Mr. W. R. Wright writes, in reference to the blowing of the new cooling tower, to say that the design upon which the tower was constructed was neither prepared nor approved by him and that he has terminated his agreement with the Council.

Municipal Wiring.—The Corporations of Ayr, Wakefield and Manchester have agreed to give financial support to the scheme of the Incorporated Municipal Electrical Association to promote a bill to authorise local authorities to undertake wiring work, to let motors on hire, &c. Northampton, Chester, Shrewsbury and Burnley Corporations and Radcliffe and Leyton Councils will give it their moral support. Sunderland Corporation are in favour of the proposal. St. Anne's-on-the-Sea Council have decided to take no action, and Bexley Heath Council will consider the matter again.

Norwich.—Application has been made to the L.G. Board for sanction to borrow £18,790 (instead of £17,783 authorised by the Council on March 15 last) for extensions of mains and services, and for an exhaust steam turbine, with condenser, steam exhaust, water pipes, &c., centrifugal pump, balancer, coal elevator, &c.

Oldham.—The borough electrical engineer (Mr. S. Wilmott Newington) has reported that extensions of generating plant will be necessary in order to meet the demand for the winter of 1911-12.

Negotiations are proceeding between the Corporation and Chadderton Council as to the terms upon which a supply of electrical energy is to be given in Chadderton district, and pending a definite agreement Oldham have obtained permission to supply eight consumers in the district.

Personal.—Mr. H. L. Tyson-Wolff (electrical engineer to the East Indian Railway Co.) returns to duty in India on Nov. 1 next.

Perth.—The city electrical engineer (Mr. J. Lambert) has been asked to report upon the question of providing mechanical stokers at the electricity works.

Portsmouth.—An inquiry was held on Friday into the application of the Corporation for sanction to borrow £24,000 for extensions of the electricity undertaking.

The town clerk (Mr. G. Hammond Etherton) said the amount required was for expenditure on mains, transformers, meters and house services during the next three years. Of the previous sanctioned loan of £22,288, there was an oustanding balance of £1,914, and assuming the Board would deduct that sum from the present application, the present sanction would be £22,086.

Digitized by Google

The INSPECTOR pointed out that the L.G. Board preferred that meters should be paid for out of revenue and not out of loans.

The superintendent (Mr. W. S. FOALE) said the revenue for the last year showed a decline, owing to concessions to consumers, the more general use of metal filament lamps and reduction in charge for public lighting (from £18 to £16 per arc lamp per annum). Instead of the flat rate, a sliding scale had been introduced, and the amount of rebates to consumers was £2,595 for last year, against £1,860 in previous year. The units sold had slightly increased by the further use of power units, but private lighting had slightly decreased. The reserve fund had nearly reached the statutory limit of 10 per cent.

Presentations.—Mr. W. Vincent Waite, late works manager to Messrs. Bruce Peebles & Co. was the guest at a dinner given in Edinburgh on 14th inst. on the occasion of his leaving the firm to start business on his own account in Cardiff. Mr. Waite was presented with a sideboard and Mrs. Waite with a silver salver as a token of appreciation from the workmen and staff. The presentation was made in the main shop by Mr. Lee Murray, general manager of the Company, and Mr. Waite feelingly acknowledged the gifts.

Mr. F. R. Batty, late manager of the Northallerton Electric Light & Power Co., who has obtained a position in London, has been presented by the directors with a cheque and by the staff with silver flower vases.

Rochdale.—In June an inquiry was held into the application of the Council for sanction to borrow £13,940 for extensions of the electricity undertaking, and the L.G. Board have now written to say that the unexpended portion of the previous loan must be used first.

The Council are recommended to double the track of the Blackwater-street tramway.

St. Pancras (London).—The chief electrical engineer (Mr. S. Baynes) has reported that for the year ending March 31, 1911, £2,000 will be required for mains, £1,700 for services and switches, and £800 for meters and indicators.

Seaton Delaval (Newcastle-on-Tyne).—Electric lighting mains are being laid in this district, and current will be supplied by the Seaton Delaval Co-operative Society, who have made arrangements with the Newcastle-on-Tyne Electric Supply Co.

School Lighting.—The Bilton Council school and the new infant school, Harrogate, are to be wired for the electric light.

Seghill.—The Council have made an agreement with the Seghill Village Coal Co. for the electric lighting of the streets.

Southampton.—The auditors (Messrs. Cash, Stone & Co.) have reported that the sums standing to credit of depreciation and renewals fund of the tramway and electric light departments on March 31 were £20,263 (increase £5,190 on previous year) and £9,815 (increase £1,925) respectively. £2,000 has been appropriated to relief of rates from the tramways and £2,424 from the electricity department.

Stoke Newington (London).—An additional transformer is to be provided at Edward's-lane sub-station, at an estimated cost of £100, and mains are to be extended at a cost of £75.

The Electricity committee has been in negotiation with the North Metropolitan Electric Power Supply Co. on the subject of a revision of the charges to private lighting consumers, and the company has agreed to the following variation, viz.: That the present rates of 7d. and 2d. on the maximum demand system be continued, and apply to the whole borough, with the proviso that, if during the six months ending March 31 next, or any subsequent year ending March 31, the average charge to the consumer shall exceed 5d. per unit, he shall be entitled to a credit (off the March quarter's account) of the amount by which his total charge for the whole period has exceeded an average of 5d. per unit. The committee has provisionally approved.

Trade Union Congress.—Several important questions affecting the engineering industries were discussed at the Trade Union Congress held at Sheffield last week. There were 501 delegates present, representing 210 societies and 1,620,715 members.

In the course of his presidential address Mr. J. HASLAM, M.P., said the present unrest in the trade union world, while a matter with which the Congress could not deal directly, was of sufficient importance to warrant him in saying a few words upon it. The principle underlying the trade union movement was that of collective bargaining, and whether that might be refused by individual employers in these days or whether the principle so almost universally accepted was put in jeopardy by sections of the men in various unions, the essential point to them was that they must do all that they could to maintain the power of collective bargaining, which, on the one hand, demanded recognition from the employers, and, on the other, equally demanded confidence in the leaders of the trade unions and the officers of the various organisations. The year had been eventful in the coming into operation for the first time in the history of the civilised world of a national system of labour exchanges. No doubt a newly established organisation, with officials fresh to the work, would have made mistakes. Criticism should be reasonable and fair, and backed up with facts which would assist the Parliamentary Committee to secure the necessary alterations in its administration and regulations which should secure to the trade unions of the country that the labour exchanges should not be used to their detriment. The Government had indicated their intention of dealing with the question of insurance against unemployment. The country had had the opportunity of reading the pronouncements made by the Permanent Secretary of the Board of Trade (Sir H. Llewellyn Smith), from which it would be gathered that the Government had some data upon which to base their calculations, and whilst they recognised that it would be impossible to establish a scheme applicable to the whole of the trades of the country, they were pleased to notice that a start had been made with those trades which were most liable to and suffered most from unemployment. That the scheme must be compulsory he thought they would all have to admit. Contributions would no doubt be asked for from the employers and from the workers, with a State guarantee and a State subsidy added, in order to make up the necessary funds for the management of a scheme applicable to the building trade and the great engineering and allied trades of this country.

Mr. Haslam also criticised the Osborne judgment and dealt with the situation created by the judgment at some length.

Resolutions were passed instructing the Parliamentary committee to circularise the unions affiliated to the Congress with a view of obtaining opinion and suggestion as to the practicability of a national federation or confederation of all trades; and to request views on the possibility of determining all industrial agreements on a given date for each year; and also to consider and report to the next Congress upon the possibility of amalgamating by industries all existing unions, with one central executive elected by the combined unions and with power to act unitedly whenever there is a strike or lock-out in any industry.

Resolutions were adopted in favour of the nationalisation of the railways, and of bringing all offices and shops under the Factory Acts.

A long discussion took place on the Osborne judgment, and eventually a resolution was adopted protesting against the judgment and claiming legislation to restore to trade unionists the right to levy contributions for the support of their Parliamentary representatives.

In regard to labour exchanges, the Parliamentary committee were instructed to take steps to secure the following regulations for their administration:—

(1) That a recognised trade union official shall, on making application to the superintendent of any labour exchange, be supplied with the name and address of, also the wages paid by, any firm offering employment through the medium of the exchange. (2) That under no circumstances should applications for situations be sent outside their own district, unless the superintendent of the exchange is first assured that the firm offering employment recognise the trade union rates and conditions of the district. (3) That the regulation governing the administration of the exchanges should stipulate that under no circumstances should the divisional superintendent or the superintendent of any exchange cause to be exhibited any notice of or entertain in any way whatever applications from firms who may have a dispute with their workpeople after such dispute has been officially notified by the trade union concerned.

Resolutions were also passed in favour of an amendment of the Trade Disputes Act so as to make it illegal for an employer during a pending strike or lock-out to house persons other than the caretaker and his family in any premises not certified as a dwelling-house, and the granting of old age pensions to foreigners who have resided for 20 years in this country.

A resolution in favour of the establishment of a central legal defence fund was carried, as was one claiming adequate representation for trade unions in the management of any scheme of compulsory State insurance for unemployment.

Truro.—Messrs. J. & W. Purves will apply for a provisional order for this district, the Council offering no opposition.

Twickenham.—The Lighting committee are considering letters from the Twickenham & Teddington Electric Supply Co. as to terms upon which they would contract for lighting the whole or a portion of the street lamps in the district.

Wakefield.—The charge for electric current for private lighting has been increased to 4½d. per unit.

Walthamstow.—The Electricity committee have decided that a 1,000 kw. mixed pressure turbine with tandem generators of 500 kw. each, condensing plant and pipe work, cooling tower, switchgear, &c., be installed at an estimated cost of £9,500. The car shed is to be extended and the alterations required to the overhead equipment are to be carried out by the tramways engineer, Mr. G. R. Spurr.

Will.—The will of the late Mr. George Flett (managing director of Dick, Kerr & Co.) has been proved, and the estate is valued at £111,653 gross, with net personality £88,775.

Wireless Telegraph Notes.—Again wireless telegraphy has been used in the capture of a "wanted," this time in home waters. A criminal lunatic escaped from the Dumfries Asylum, walked to Liverpool, and then took passage in the "Viking" for Douglas. He was recognised on the vessel by a Manx police inspector, who sent a wireless message from the ship in mid-channel to Douglas, where the prisoner, a desperate man, was seized on the pier by the police.

In the military manœuvres which have been carried out in Hampshire wireless telegraphy has formed a prominent feature, and the Wireless Telegraph Company of Engineers has been provided with one of the most effective field station equipments of its kind in existence. This equipment is extremely portable (it can be erected in

Digitized by Google

17 minutes and dismantled and removed in even less time), has a radius of 60 miles and has been found to work with extreme simplicity and accuracy.

It is now reported that in the attempts made during the nava manœuvres in Torbay, S. Devon, communication was well established between the cruiser "Bonaventure" and a submarine vessel, and that by this success the utility of the submarine in actual warfare is largely increased. The submarine with which communication was satisfactorily established was the "D1," built by Messrs. Vickers, Sons & Maxim, and delivered to the Admiralty 12 months ago. This vessel, which is the largest British vessel of the kind, and the first to be fitted with a wireless installation, was submerged during the experiment as far down as the periscope, which reaches about halfway up the vessel's mast. The labours of all concerned are now being devoted to perfecting a means by which the submarine boat can establish communication with other ships, and so become, as it were, self-reliant. An excellent view of submarine D1 appeared in the "Daily Telegraph" for Sept. 21.

Weymouth.—The Electric Lighting committee recommended that application be made for a provisional order to authorise the construction of tramways in the district at an estimated cost of £27000. The report was, however, withdrawn and another scheme is to be prepared.

Workhouse Lighting.—Owing to the cost of gas lighting at Hastings workhouse the Guardians have instructed the Building and Repairs committee to obtain an estimate for wiring the whole of the workhouse buildings, and the Clerk has been requested to ascertain if the Corporation would be prepared to supply electric current for lighting at the same cost as is now paid for gas.

Llandilo Council have decided to extend the electric light mains to the new workhouse infirmary at a cost of £100, provided the Guardians guarantee to take a minimum of 500 units per annum for at least five years, and pay 6d. per unit, subject to a reduction to 4½d. per unit in the event of 1,000 units per annum being consumed.

Yeovil.—The Council will take no action in regard to a proposed application by Messrs. J. & W. Purves, for a provisional electric lighting order.

Social Reunion.—The employés of Dublin Corporation electricity supply department held their social reunion on the 15th inst., when the Lord Mayor presided over a good attendance. Among those present were the chairman of the Lighting committee (Ald. Dr. McWalter), the city electrical engineer (Mr. Mark Ruddle), Mr. G. Archer (chief assistant), Mr. L. J. Kettle (superintendent of Pigeon House generating station) and Mr. E. Mayne (mains engineer).

The CHAIRMAN congratulated the company on the fact that their first "smoker" was so well attended. Mr. Jas. Lurring was accompanist, and a number of talented artistes lent their assistance to make the evening a very enjoyable one. In bringing the proceedings to a close the Lord Mayor paid a special tribute to the energy displayed by the managing committee and its assistants, and to the splendid talent procurable in the Dublin electricity department. A vote of thanks to the Lord Mayor was heartily accorded and his health was drunk. The healths of Ald. McWalter, and Messrs. Ruddle, Archer, Kettle and Mayne were also drunk and responded to. The managing committee were Messrs. T. H. Lurring, F. Foster, and F. Sheehan, with Messrs. H. J. Mayne and J. McNamee hon. secs. The stewards were Messrs. H. Donohue, J. Melia, J. Keogh and J. Reilly.

COLONIAL AND FOREIGN NOTES.

Australasia.—The "Australian Mining and Engineering Review" says *Bunbury* (W. Australia) municipality have purchased the Bunbury electricity works of Messrs. Splatt, Wall & Co., at £7,374.

Wordend and Newham (Victoria) Shire Council have decided to equip electricity works at a cost of about £2,000.

The superintendent of *Sydney* tramways recently presented to the Public Works committee statistics showing that in the year 1909-10 traffic receipts were £1,016,724 (compared with £315,930 in 1900), the miles open being 94 (against 43½); 174,001,848 (53,470,533) passengers were carried and 17,742,500 (3,106,185) car-miles run. By including North Sydney the total number of passengers carried is increased by 48,978,286.

Perth (W. Australia) City Council are promoting a Bill authorising them to borrow money for purchasing the undertaking of the Perth Gas Co., which also supplies electrical energy.

The electric lighting of *Nhill* (Victoria) railway station is to be undertaken by the local electric light company.

A recent plebiscite of the ratepayers resulted in 917 votes for and 1,664 against the installation of steam auxiliary plant at *Launceston* (Tasmania) electric power station at a cost of £6,000. The Council therefore decided not to proceed with the installation of the steam auxiliary and invited the advice of the Government hydraulic engineer, Mr. W. Reid Bell, on the best means of increasing the water power. It is understood Mr. Bell will go into the matter in due course.

Creswick (Victoria) Council have decided to approve a proposal submitted by Mr. Buchanan Black for the generation of electrical energy by means of the water power available at Braggs' Flat. At this place (6 miles east of Creswick) there is a natural reservoir which would permit of sufficient storage to supply 3,000 H.P. during four months in the year. It is proposed to instal two 3,000 H.P. Pelton turbines each coupled to a 2,500 kw. generator.

Tatura (Victoria) Butter Factory Co. are applying for an Order in Council authorising them to supply electrical energy for public and private purposes, the estimated capital expenditure being £2,000.

The "Australian Mining Standard" states that Mr. Donald Mackinnon recently referred (in the Victoria Legislative Assembly) to the subject of the electrification of the Melbourne suburban railways, and demanded prompt action. The premier (Mr. Murray) replied that electrification could not be applied immediately. Mr. Mackinnon retorted that electricity would have to come, whatever predilections one might have about any particular form of power. Mr. Prendergast (Leader of the Opposition) said the Commissioners talked of doubling the railway system, but he hoped no expenditure in that direction would be permitted until they had come to a decision as to electrification. Mr. Murray said whatever improvements were made would be of such a character that they might be used when the electrification came. There was no question about the electrification of the suburban railways—that must come. They did not propose to appoint a commission to inquire into that, as they had sufficient information in Mr. Merz's report. The Government were alive to the question, and as little delay as possible would occur.

Ararat (Victoria) Council are considering the question of establishing municipal electricity works.

At a meeting of the local butter company at *Mortlake* (Victoria) a resolution to undertake the supply of electrical energy in the town was lost because it was not supported by a three-fourths majority. There were 58 votes for and 33 against.

The Bellambi Coal Co. have offered to supply to *Bulli* (N.S.W.) Shire Council electrical energy for lighting in Wallongong, and also to supply *North Illawarra* Municipality with current for use in Corrimal.

Manly (N.S.W.) Council are proceeding with the erection of the generating plant for supplying current for working the tramway extension to the Spit, which will connect up with the North Sydney tramways, and is expected to be ready for working in December.

Footscray (Victoria) City Council recently decided to adopt the electric light and power scheme recommended by their Lighting committee. The Council will purchase and erect the poles, wires, lamps, &c., at a cost of £8,000, and take current from Melbourne Council. The prices to be charged to private consumers will be 5d. per unit for lighting and 2d. for power.

Dr. Alex. Graham Bell recently gave evidence before the Postal Commission, at the Federal Parliament House, *Melbourne*, on the Sydney telephone service. While admitting that his observations of the Sydney service showed that much was still desired to make it efficient, many of the complaints of delay were due to the tardiness of subscribers in replying when called up. The average time occupied in giving the connection was 8 seconds, but the average time before a reply was obtained was 32 seconds. Dr. Bell considers metallic circuits and underground wires essential to successful telephony in a city. He considers that the proposed toll system is on a fair basis, but thinks it necessary, before judging of the justice of the rates, to overhaul the departmental accounts (as was done for New South Wales recently) to ascertain what the system has cost.

The Premier of South Australia (Mr. Verran) recently promised to obtain a report as to the suitability of the Brennan monorail system for a light railway for the carriage of farm produce.

The Corporation of St. Peter's (a suburb of *Adelaide*) recently passed a resolution in support of proposed amendments of the Tramway Trust's Act to enable the trust to sell electrical energy for lighting and power. Coun. Crowley, who moved the resolution, said Adelaide Council had acted unfairly to outside municipalities in suggesting that it should purchase the Electric Light & Supply Co.'s works. Adelaide Council should have all the surburban Corporations in with it in the purchase scheme.

Naurkah (Victoria) Council are obtaining a report from an expert on the subject of electricity supply.

The Victorian Institute of Electrical Engineers has now over 100 members and associates.

A bill has been introduced in the Tasmanian Parliament to authorise the Derwent Mfg. Co. to generate and supply electrical energy at any place in Tasmania outside a radius of 10 miles of Launceston. It is proposed to use water power from the river Derwent, near Macquairie Plains station, and to manufacture carbide of calcium in addition to generating and supplying electric power.

The Tasmanian Parliament has passed a resolution to advance the money necessary for constructing electric tramways from Hobart to Huonville, with a branch to Kingston, and from Huonville to Lovett and Geeveston, provided the local authorities accept certain responsibilities. At a recent public meeting Geeveston ratepayers decided not to support the scheme in its present form, and Mr. Bennett, who supported the motion, said if the scheme was so good as had been stated in Parliament it needed no guarantee from the ratepayers, and he thought that it would not be fair to ask the Huon ratepayers for a guarantee, as they had contributed towards the cost of other railways in central and north Tasmania.

Longford (Tasmania) electricity works were formally opened on Aug. 8.

Kadina (S. Australia) Council are advised to put in an additional 100 H.P. of generating plant, as the present sets are fully loaded.

Digitized by Google

Bombay Hydro-Electric Scheme.—It is announced that the Ghats hydro-electric scheme will be carried out and financed by an Indian company. The capital is set down at Rs. 1,70,00,000 (£1,250,000), of which nearly three-quarters have been subscribed. The Maharaja of Bhaunagar has taken up 20 lakhs and the Gaekwar of Baroda 10 lakhs. The scheme provides for the utilisation of two or three large lakes at Lanauli and the installation of an electric power plant at the bottom of the ghats, and the energy will be transmitted to mills and factories in the Bombay district. Originally it was proposed to carry out a much larger scheme, which has now been divided into sections each of 10,000 H.P. The present proposal is to instal three units (one in reserve) and to extend the plant as circumstances require it. The cost of providing 50,000 H.P. would be about Rs.1,1,00,00,000. The Bombay Electric Supply & Tramway Co. owns and works an undertaking for supplying electricity in Bombay, but the new company will only supply electricity in bulk and for power.

Brazil.—Since the electrification of the Porto Alegre tramways the Companhia Força e Luz has found it necessary to double a portion of the lines, owing to increased traffic. The company has contracted with the British firm who carried out the electrification of the tramways for the erection and equipment of electric lighting and power works for private supply. The new works will compete with the present lighting company and the municipality. Underground distribution will be adopted.

China.—Mr. W. P. Ker (Commercial Attaché to the British Legation at Peking), in his report on the foreign trade of China for 1909, writes :—

The Chinese are convinced that foreign imports drain their country of its wealth, and they seek to curtail the privileges of the foreign trader, but the establishment of factories affords an ever-widening opening for the use of imported machinery. The imports of electrical materials and machinery have been considerably reduced. Progress, however, continues to be made throughout the Empire in undertakings requiring machinery. During 1909 electric lighting contracts were given out for new installations at Chungking, Chengtu, Changsha, Nanking and Ningpo and for extensions at Shanghai, Hankow, Peking, Swatow, Moukden and other places. Negotiations were going on at the beginning of 1910 for a large installation at Hangchow and for installations in several cities in Manchuria. Indeed, there may be said to be an electric lighting project in every city in China, the only difficulty being to find funds for carrying such projects into execution. Almost all contracts require to be financed by the contractors, and British firms, finding British manufacturers unwilling to supply plant except for cash down, have sometimes co-operated with German firms, the latter arranging the finance in return for being allowed to participate. Thus several of the contracts mentioned above are for British engines and boilers and German dynamos. Payment is generally spread over a period of two or three years on proper security being given.

An electric tramway scheme for Canton is under contemplation, a considerable extension of the telephone system in that city has been recently carried out, and preparations are being made for inaugurating telephone services at Chengtu, at Wuhu and in the provinces of Kiangsi and Chekiang. All the private shares in the Imperial Chinese telegraphs have now been redeemed, and the administration is completely under Government control, partly Imperial and partly provincial. Extensions of the system continue to be made, the most important effected during 1909 being the direct Peking-Hankow line along the railway, on which fast automatic Wheatstone working has been established. The statistics for 1909 show that there are 1,099 miles of submarine lines and 25,273 of aerial line. The head office staff number 112, the general staff 3,473 and the line staff 2,833. 807,841 telegrams were handled. The receipts were $838,733, and the expenditure $479,816. There are 1,171 instruments in use, of which 22 are Wheatstone automatic and five wireless. A reduction of telegraph charges by 20 per cent. was effected in 1909. The programme of the Board of Communications for 1911 includes preparations for installing wireless telegraphy along the coast.

Chinese imports in 1909 included electrical material and fittings to the value of £177,676 (39 per cent. from the United Kingdom and the remainder from Germany, Japan and Belgium), compared with £232,571 and £189,871 in 1908 and 1907; machinery and fittings £733,567 (47 per cent. from the United Kingdom and the remainder from Germany, U.S.A. and Belgium); telegraph materials £45,199 (from the U.K. and Japan), compared with £47,611 and £60,237.

Consul Hausser (Swatow) writes :—

Instead of the electric tram line mentioned in last year's report, it is now proposed to construct a light railway to connect Swatow with the neighbouring city of Ch'eng-Hai, about 10 miles distant. The cost is estimated at $230,000, not including bridge work. No foreigner is to be allowed to be a shareholder of the company. Similar restrictions are made in the case of other native companies.

Inquiries have been made with a view to the extension of the telegraph line from Chao-chow Fu to Kia Ying Chow, a distance of 40 miles. The Swatow Electric Light Co., capital $175,000, has completed its buildings and the plant is in working order and giving satisfactory results.

Constantinople.—It is announced that the concession for the erection of electricity supply and gas works has been given to Messrs. Ganz & Co., Budapest.

India.—"Indian Engineering" says the Burma Public Works Department have created a special subordinate establishment for carrying out electrical work in Government buildings in Rangoon, Maymyo and Mandalay. The sanctioned staff includes two senior electricians each at R270 per month (rising to R420), one assistant R160 (rising to R260), and one junior assistant R100 (rising to R160), in addition to the allowances granted to upper subordinates of corresponding rank.

Swiss and German Electrical Engineering Combine.—It is stated that it has been arranged to make an exchange of capital at the rate of one 1,250 fr. share of Brown, Boveri & Co. of Baden for four 500 fr. shares of the Elektrizitats-Gesellschaft, Alioth, Basle (provided 60 per cent. of the latter company's shares are so transferred), and one share of the Brown, Boveri Co. for one share of the Isaria Co., Munich. It is thought that the acquisition of the Isaria Co. will be of considerable assistance in dealing with the South German trade. The capital of the Brown, Boveri Co. is to be increased from 20 to 28 million francs.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Bradford.—The accounts of the electricity department for the year ended March 31 have been published and show a total annual income of £113,983, of which £107,222 was received from the sale of current for private and public lighting, power and traction, £2,861 from rental of meters, cables, &c., and £6,756 from the hire of motors, arc lamps, &c.

The total working expenses (£50,847) included £25,915 for cost of generation (of which £11,856 was for coal and £978 for steam supplied by destructor department), £4,574 for distribution, £5,485 for wages, materials, &c., of motor hiring department, £501 for public lamp maintenance, £253 for rent, £6,817 for rates and taxes and £6,272 for management expenses. The gross profit was £63,135, out of which interest on loans, income tax, &c. (£22,333), and sinking fund contributions (£33,403) were paid, leaving a net profit of £7,399. The gross capital expended is £796,722, an increase of £27,362 on the year. There are 2,570 consumers, with the equivalent of 469,352 8 c.p. lamps connected. 21,521,007 units were generated and 18,737,857 units sold, including 2,717,315 for private and 134,410 for public lighting, 2,725,858 units for power and heat, 9,582,103 for traction (including 141,709 for lighting sheds, &c.) and 3,578,171 bulk supply. The maximum simultaneous load was 5,839 kw. for lighting and power and 2,083 kw. for traction, a total of 7,922 kw. The capacity of the generating plant is 8,180 kw., but in addition a 700 kw. turbine has been installed temporarily pending completion of two 3,000 kw. Curtis turbines and equipment. There are 69 public arc lamps. The number of motors connected is 1,769 (of 9,582 H.P.), of which 858 (of 3,776 H.P.) are on hire. There are 224 motors (2,812 B.H.P.) which are supplied with energy on bulk supply terms.

Greenock.—The total revenue of the electricity department for the year ended June 30 was £29,017, including £7,834 from the sale of current for private lighting, £15,168 for power, £947 for public lighting and £4,220 from the Greenock & Port Glasgow Tramways Co.

Total expenses were £14,672, leaving gross profit £14,345. Interest on loans and mortgages came to £4,155, instalments of loan, &c., repaid to £5,863, and depreciation to £3,248, and after placing £1,000 to reserve the balance in hand was £2,026. The total capital expended was £192,192, an increase of £15,384 during the past year. 5,727,183 units were generated and 5,096,128 units sold, including 69,645 units supplied for public lighting, 4,326,841 sold to private consumers by meters, and 699,642 to the local tramway company. There are 53 public arc lamps and the total maximum supply demanded was 2,590 kw., against 2,320kw.

Newport (Mon.).—The accounts of the electricity supply and tramways departments for the year ended March 31 have been issued, and in the accompanying report of the borough electrical engineer and tramways manager (Mr. H. Collings Bishop) it is stated that both departments made good progress during the year.

The revenue of the electricity department from the sale of current was £30,043 (1·80d. per unit sold), against £27,710 (1·84d.), and the total costs were £13,526 (0·81d.), against £13,130 (0·86d.). The gross receipts (including meter rent, sales, &c.) were £35,328, and the total expenditure £16,671, leaving a gross profit of £18,657. Interest absorbed £8,871 and sinking fund, &c., £9,410, leaving a net profit of £376, against a deficit of £1,469. The capital expenditure is £278,887, an increase of £6,904 during the year. 4,012,909 units were sold (against 3,615,783), including 916,979 for private lighting (974,721), 701,178 for power (915,601), 537,770 for public lighting (468,885), 1,320,393 for traction (1,215,794), 50,278 for heating (40,782) and 486,311 bulk supply. The equivalent of 187,703 8 c.p. lamps is connected (against 161,773); the maximum load was 2,324 kw. (1,950 kw.), and the load factor 19 per cent. (21 per cent.).

The total receipts of the tramways department were £35,109, and the working costs £23,687. The gross profit was £11,422, and after paying interest (£5,829) and sinking fund (£3,271) there was a net profit of £2,322. The total passengers carried 8,134,845, and the total car-miles run 810,359. The capital expended is £192,828, an increase of £2,566.

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1910 Edition of the Big Blue Book is READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 16th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1910 Big Blue Book, making it the most complete work of the kind ever published.

TENDERS INVITED.

Tenders are invited by EDINBURGH Corporation for three steam turbines and d.c. generators, each of 1,200 kw., and condensing plant and interior parts of cooling towers, for their Dewar-place electricity station. Copies of specification, forms of tender, &c., from the engineer, Mr. F. A. Newington, Dewar-place, Edinburgh, and specifications, conditions and drawings may be seen at, but not obtained from, the offices of the consulting engineer, Sir Alexander Kennedy, 17, Victoria-street, London, S.W. Tenders must be delivered at the office of the town clerk, Mr. Thomas Hunter, W.S., City-chambers, Edinburgh, by Oct. 10.

The Electric Light committee of the City of SHEFFIELD invite tenders for supply of steam turbine alternator, exciter, condensing plant, pumps and other accessories, and three water-tube boilers, economisers, induced draught fan, steel chimney, &c. Specifications, forms of tender and general conditions from the general manager and engineer, Mr. S. E. Fedden, Corporation Electric Supply Department, Commercial-street, Sheffield, where tenders are to be delivered by 10 a.m. Sept. 30.

The Directors of the METROPOLITAN RAILWAY Co. are prepared to receive tenders for the supply of general stores during 12 months ending Oct. 31, 1911. Forms of tender (No. 13, electric wires and cables; No. 14, electric lamps, carbons, switches, fuses, telephones, coils, &c.; and No. 15, insulating materials) from the Secretary, 32, Westbourne-terrace, London, W., to whom tenders by 10 a.m. Oct. 3.

By command of the POSTMASTER-GENERAL tenders will be received until noon, Monday, Sept. 26 for supply of Swedish, Norwegian, Finland or Russian red fir telegraph poles to be delivered at certain ports in the United Kingdom; also for creosoting, &c., telegraph poles. Forms of tender, &c., from the Controller of Stores, 17-19, Bedford-street, London, W.C.

LONDON County Council require tenders by 11 a.m. Oct. 11, for the road work and platelaying required for the reconstruction of the Highgate-road tramways for the conduit system, and for paving works of street widenings. Specifications from the Chief Engineer.

LONDON County Council also want tenders by 11 a.m. Oct. 5 for electrical installation work at the Poplar Coroner's Court and Hoxton House Schools, Shoreditch. Specifications, &c., from the Chief Engineer, Spring Gardens, S.W.

YORK Electricity committee want tenders by Oct. 7 for 12 months' supply of carbons, carbon brushes, carbon filament lamps, meters and time switches, motors, &c. Forms of tender, &c., from the City Electrical Engineer.

FOLKESTONE Electricity Supply Co. want tenders for the erection of natural draught cooling tower. Particulars from the Manager, at Folkestone.

HACKNEY (London) Council require tenders by 7 p.m. Oct. 13 for supply of 90,000 pairs of white open-type arc lamp carbons. Specifications, &c., from the Town Clerk.

ISLINGTON (London) Guardians want tenders (by 4 p.m. Oct. 6) for supply and fixing of bells, fire alarms and telephones at the Workhouse, Upper Holloway, N. Specification from the Master of the Workhouse.

The Isle of Thanet Electric Tramways & Lighting Co. (ST. PETERS, Kent) want tenders for 12 months' supply of stores. Forms of tender from the Engineer and Manager.

RHYL Council invite tenders for 12 months' supply of fuel oil from Oct. 1. Tenders to the Clerk by 26th inst.

Tenders are invited for supply of telegraph and telephone cable (schedule No. 284) and insulators (schedules Nos. 373 and 374) to the Postmaster-General's Department, VICTORIA. Tender forms and particulars at the Commonwealth Offices, 72, Victoria-street, London, S.W.

Tenders are invited up to noon Oct. 17 for the supply of telegraph and telephone instruments and material (as per schedules 1 to 9) to the Postmaster-General's Department in TASMANIA. Tender forms and specifications at the office of the High Commissioner, 72, Victoria-street, London, S.W.

The Deputy Postmaster-General, MELBOURNE, will receive tenders until 3 p.m. Oct. 18 for supply of 23 miles of telephone cable (specification 284) and 500 composition insulators (specification 374) and until 3 p.m. Oct. 25 for 10,000 Cordeau insulators (schedule 373). Specifications, &c., from 72, Victoria-street, London, S.W. Local representation is necessary.

Tenders are invited up to Oct. 5 for the supply of 5,000 porcelain insulators to the Postmaster-General's Department in NEW SOUTH WALES. Tender forms and specifications from the Commonwealth Office, London.

Tenders are invited up to Oct. 4 for the supply of telegraph and telephone insulators to the Postmaster-General's Department in all the States of the Commonwealth of AUSTRALIA. Tender forms at the Commonwealth Offices, London.

Tenders are invited up to Oct. 4 for the supply of telegraph and telephone material to the Postmaster-General's Department in VICTORIA. Forms of tender, &c., from the Commonwealth Offices, London.

Tenders are invited up to Sept. 27 for the supply of electric lamps to the Postmaster-General's Department in VICTORIA. Forms of tender, &c., from the Commonwealth Offices, 72, Victoria-street, London, S.W.

ADELAIDE (S. Australia) Municipal Tramways Trust want tenders by Oct. 11 for supply of 1,750 tons of tramrails, 150,000 dogspikes and 1,200 tiebars and by Oct. 18 for bonding material.

Tenders will be received by the Minister of Telegraphs, G.P.O., WELLINGTON, N.Z., up to noon Dec. 15, 1910, for supply and erection of installations of wireless telegraphy at or near Doubtless Bay, Gisborne, Cape Farewell, Sumner (near Christchurch) and Bluff. Specification, conditions, &c., at the office of the Superintendent of Electric Lines, G.P.O., Wellington, and the office of the High Commissioner, 13, Victoria-street, London, S.W. Tenders must state the name of the country in which the apparatus, &c., will be manufactured.

The Ministry of Public Works, CAIRO, require tenders for electrical installations and refrigerating plant for the lunatic asylum in course of construction at Khanka. Specifications from the Chief of the Administrative Service, Ministry of Public Works, Cairo. Stamped paper for tenders is obtainable from Mr. A. L. Webb, Westminster, S.W. Tenders by noon Oct. 20. Legal domicile at Cairo is necessary in the case of this contract, and to obtain temporary domicile British firms must, before electing such domicile, formally advise the Consulate at Cairo of intention to do so, formally authorise the Consulate on their behalf and inform the Consulate of the address to which documents should be forwarded.

Tenders will be received at the Ministere des Colonies, rue Oudinot, 27, Paris, until Oct. 14 for the supply and laying of a submarine cable between LIBREVILLE and LOANGO (French Congo). Deposit of £2,000 required with all tenders, to be increased to £4,000 with successful tender.

Tenders are wanted by noon Oct. 31 for supply and erection of machinery, &c., for electricity supply and water supply systems for the town of BENI-SOUEF (Egypt). Particulars may be obtained from Mr. A. L. Webb, C.M.G., Queen Anne's-chambers, London, S.W. Local representation is necessary.

The Turkish Ministry of Commerce and Public Works want tenders by Oct. 28 (Nov. 10) for a concession for the construction and working of electric tramways in CONSTANTINOPLE and suburbs. A deposit of £13,500 (sterling) is required with each tender. Local representa-

Digitized by Google

tion is essential. Copy of specification (in French) may be seen at 73, Basinghall-street, London, E.C.

MOSTAR (Austria-Hungary) Municipality require tenders by Oct. 1 for the installation of electrical generating plant. Specification (in German) can be seen at 73, Basinghall-street, London, E.C.

The "North China Herald" states that SHANGHAI electricity department require tenders by noon Oct. 10 for supply of electric heating and cooking appliances, and by noon Oct. 20 for 10,700 carbon and 15,000 metal filament lamps. Specifications from the Electricity Works, 31, Fearon-road, Shanghai.

The NORWEGIAN STATE RAILWAYS DEPARTMENT require tenders by 3 p.m. Sept. 30 for the supply of two 35-ton electric cranes. Specifications, &c., (in Norwegian) may be seen at 73, Basinghall-street, London, E.C.

Tenders are invited for the electric lighting of NAGYAROVAR (Hungary). Tenders to the Town Hall by Sept. 27.

Tenders are invited for the supply to the Danish State Railways Administration of 1,656 accumulators for the lighting of railway carriages. Tenders, marked "Tilbud paa Levering af Akkumulatorer," will be received at "Direktören for Maskinafdelingen, de Danske Statsbaner, Gl. Kongevej 1D, 3 Sal," COPENHAGEN, up to noon on Sept. 26. Specification, &c. (in Danish), may be seen by British makers at the Board of Trade offices, 73, Basinghall-street, London, E.C.

TENDERS RECEIVED AND ACCEPTED.

London County Council received the following tenders for wiring the central car repair depot (second section):—

E. Lawrance & Sons (*accepted*), **£1,702. 17s. 3d.**; Barlow Bros. & Co., £2,425. 16s. 4d.; Gordon Lawson, £2,320. 2s. 6d; G. Weston & Sons, £2,043. 12s. 9d.; Pinching & Walton, £2,035. 10s.; E. Newbald & Co., £2,024. 8s. 5d.; Tilley Bros., £1,888. 12s. 6d.; Johnson & Phillips, £1,877. 3s.; G. E. Taylor & Co., £1,863. 19s. 6d.; Central Motor Engineering Co., £1,571. 8s. 3d.

Sydney (N.S.W.) Electric Lighting committee have accepted the tenders of Babcock & Wilcox for coal and ash-handling plant, £5,887. 5s.; Bullivant's Australian Co., steel suspension cable, £306; Stewarts & Lloyds, 75 steel poles, £103. 2s. 6d.; W. T. Henley's Co., 15 miles of cables (for 11,000 volts), £4,495 (instead of the original quotation of £4,760).

Siemens-Schuckert Werke have the contract for the 1,200 kw. Zoelly steam turbine and electric generator to be put in at the Drammen (Norway) municipal electricity works. The turbine will be supplied by Escher, Wyss & Co.

West Ham Education committee have accepted the tender of J. T Halsey (at £287. 17s. 6d.) for wiring West Silvertown school, and that of Mayfield & Co. (at £21. 7s. 4d.) for the extension of the telephone service in the municipal central secondary school.

Southwark Council has accepted the tender of the British Insulated & Helsby Cables Co. for 220 yds. 0·3 triple concentric cable (£105. 7s. 6d.), and that of the Western Electric Co. for 440 yds. 0·1 triple concentric cable (£88) and 440 yds. 0·05 cable (£60).

Sydney Corporation have received the following tenders for h.t. and l.t. switchgear: Ferranti Limited £2,719 16s. 8d. Noyes Bros., £2,813, Australian General Electric Co., £3,137, Siemens Bros. Dynamo Works £3,561.

Melbourne Corporation have accepted the tenders of Bevan & Edwards for machine tools (£122), Evershed & Vignoles, one bridge megger (£38), and E. Campbell & Son, hot well tank and staging (£83).

Rawtenstall Council have accepted the following tenders:—

D. P. Battery Co., maintenance of battery for 10 years; Crompton & Co., negative booster; Whipp & Bourne, switchboard panels.

Birkenhead Council have accepted the tender of Willans & Robinson for a mixed pressure turbine, coupled to an Electric Construction Co. dynamo, at £2,917.

Newcastle Emlyn Council have accepted the tender of the local Electric Supply Co. for public lighting from Sept. 1 until April 30, 1911.

Crewe Council have accepted the tender of Carrington & Button for wiring the new boys' school and extensions, at £147.

Brighton Guardians have accepted the tender of Adams Bros. for electrical fittings, at £32. 4s.

Hitchin Council have accepted the tender of J. Smallwood for wiring the Town Hall at £65.

Yarmouth (I.W.) Town Trust have accepted the tender of the Isle of Wight Electric Light & Power Co. for public lighting.

Wakefield Guardians have accepted the tender of the Wakefield Electrical Engineering Co. for electrical works for six months.

"Francis" Turbines.—Messrs. Jas. Gordon & Co. report that they have received orders from British Columbia for three spiral case Francis turbines (each to give 950 H.P. under a fall of 120 ft.). They are being supplied with patent oil-pressure governors, throttle valves and other accessories for direct coupling to a.c. generators.

Government Contracts.—The following tenders were accepted during August by the British Government Departments:—

War Office.—Babcock & Wilcox, water-tube boilers; H. Morris & Bastert, cranes; Lancashire Dynamo & Motor Co., re-winding of crane motors, &c.; British Westinghouse Co., switchboards, &c.; and Electric & General Lighting Engineering Co., internal wiring.

India Office.—Lancashire Dynamo Co., carbon brushes; Laurence Scott & Co., motors; Worthington Pump Co., pumps; British L. M. Ericsson Co., telephones; Elliott Bros., transmitters, &c.

General Post Office.—Callender's Co. and Johnson & Phillips, paper-core cable; Western Electric Co., retardation coils; T. Bolton & Sons, British Insulated & Helsby Cables, Elliotts' Metal Co., R. Johnson & Nephew, Shropshire Iron Co., F. Smith & Co. (London Electric Wire Co. & Smiths, Ltd.), and Wilkes, Son & Mapplebeck, copper wire; Davidson & Co., 11 electric fans for new G.P.O. building, London; A. W. Penrose & Co., eight electric lifts for head P.O., Edinburgh; W. Dobson, laying and jointing cast-iron pipes and earthenware ducts in Glasgow and Bennie & Thompson and Hodge & Sons for similar work between Worcester and Gloucester.

H.M. Office of Works.—Siemens Bros. & Co., electric mains for Victoria and Albert Museum and new Meteorological Office, London; and Browett, Lindley & Co., generating set for South Kensington generating station.

Commonwealth Tenders.—The Postmaster-General's Department (Perth) have accepted the following tenders:—

Unbehaun & Johnstone, telephone switchboard cable; Thornton & Watson, wooden spindles for insulators; India Rubber, Gutta Percha & Telegraph Works Co., resistance coils; Western Electric Co., main distributing frame for Cottesloe telephone exchange; Jas. Vincent, filling manhole covers in Trinadad composition; and J. M. Ferguson (Ltd.), extension bells, condensers, carbon diaphragms, generators, microtelephones, nuts, metallic plugs, receivers, registers, portable telephone sets and telephone operators' outfits.

BUSINESS NOTICES.

The Vieta Electrical Co. have moved their works and offices to 60, Queen's-road, Battersea, S.W.

The Cie Watt Appareillage pour Lumière et Force (soc. anon.) inform us that their manager (M. L. Flesch) has resigned in order to take up consulting work and to act as representative of industrial firms. M. L. Sogue! succeeds M. Flesch as manager of the company.

Sale by Auction.—Messrs. Fuller, Horsey, Sons & Cassell will sell by auction at H.M. Dockyard, Devonport, on Tuesday, Oct. 11, and following days, at 11 a.m. each day, quantities of scrap iron, mild scrap steel, brass, copper, manganese bronze, zinc and other metals, 106 tons electric cable, 26 boats' boilers and engines, three engines and dynamos, electrical gear and stores, two overhead travellers, machine tools, lathes, &c. May be viewed three working days prior to and on mornings of sale. Catalogues (6d. each) at the Dockyard, or of the auctioneers, 11, Billiter-square, London, E.C. See also an advertisement.

Patents Development.—The owners of patents No. 23,501/1899, relating to "Improvements in vacuum table lighting," and No. 12,582/1902, relating to an "Improved system of electric lighting," desire to negotiate with electrical engineers with the view of granting licences. Information from Messrs. Lloyd Wise & Co., 46, Lincoln's Inn Fields, London, W.C.

The proprietor of patent No. 20,324/1902, for "Improvements in conduit for electric cables," desires to grant manufacturing licences to interested parties. Applications to Mr. C. Lean, 231, Strand, London, W.C.

Theatre Lighting.—As stated in our last issue (p. 966) the contract for the complete electrical equipment of the Palladium Theatre of Varieties, London, has been secured by Messrs. Siemens Brothers Dynamo Works. The theatre will be lighted throughout by Siemens fittings and Tantalum lamps, and the circuits protected by Siemens "Zed" fuses. "Stannos" wires have been specified for the wiring, which has been sublet to Messrs. Rashleigh Phipps & Co. It is intended that the theatre shall be equipped with the most up-to-date and efficient system of illumination and lighting effects.

G.C.R. Journal.—The "Great Central Railway Journal" is a monthly publication which deals with the happenings and with the business of the railway whose title it bears, and the information contained in the September issue which we have before us is of more than G.C. interest. The correspondence is a very healthy item, and the liberty to discuss questions of interest to the officials, staff and operators on the line is, apparently, unlimited. There are many more pretentious publications which can show less reason for their existence than the "Great Central Railway Journal," the get-up and arrangement of which reflects credit upon all concerned.

Digitized by Google

CATALOGUES, &c.

ELECTRIC MOTOR SYREN.—We have received from Messrs. Siemens Bros. & Co. a catalogue dealing with this subject in which the various apparatus coming under this heading is briefly described. These syrens are motor driven and can be fitted with devices by means of which a code of signals can be given if desired.

LIGHTNING PROTECTOR.—Messrs. Siemens Bros. & Co. have ready a pamphlet describing an instrument protector which secures telephone instruments against damage by lightning discharges and high tension currents.

GILBERT ARC LAMPS.—The Gilbert Arc Lamp Co. have issued an artistic catalogue dealing with the various types of their arc lamps. The chief features of this catalogue are dealt with at some length on page 138 of the INDUSTRIAL SUPPLEMENT published with this issue of THE ELECTRICIAN.

VENTILATORS FOR UNDERGROUND CABLE BOXES.—Messrs. Bullers (Ltd.) are issuing a pamphlet describing the various details of a ventilator they have designed, by the use of which it is claimed underground cable boxes and pits and transformer chambers may be kept clear of explosive gases, while at the same time good ventilation is secured, and the boxes are not flooded by surface water.

HAND-SHIELD PLUGS.—We have to acknowledge from the British Central Electric Co. details of a new three-pin hand-shield plug, designed to comply with Home Office Regulations. It is provided with ordinary terminals, and is so designed that it can only be inserted into the socket in one way, so that all danger of shock is avoided.

MINING EQUIPMENT.—The Adnil Electric Co. forward a catalogue illustrating and describing numerous apparatus which they manufacture for use in mining work.

BANKRUPTCIES, LIQUIDATIONS, &c.

The first meeting of creditors of Jas. D. M. Morton, electrical engineer, Nettleton-road, Mirfield, will take place on Sept. 27 at Bank Chambers, Corporation-street, Dewsbury, and the public examination on Oct. 4 at the County Court House, Dewsbury.

A dividend is to be paid to creditors of Joseph Grace Cunnington and Harry P. Allison (trading as Laing, Wharton & Cunnington), electrical enigneers and contractors, 7, Great Newport-street, London, W.C. Claims to Mr. A. Page, 28, King-street, Cheapside, London, E.C., by Sept. 30.

A dividend is to be paid to creditors of Alan McAlpin, electrical engineer, 44, Cank-street, Leicester, and Cumbergate, Peterborough. Claims to Mr. L. V. Wyke, 24, Friar-street, Leicester, by Oct. 4.

The trustee (Mr. W. F. J. Hunt, Cambridge Junction, High-street, Portsmouth) in the bankruptcy of Hy. K. P. Barham (trading as the South of England Electrical Engineering Co.), 60, Fratton-road, Portsmouth, has been released.

The trustee (Mr. Chas. Scott, Station-road, Gloucester) in the bankruptcy of Walter S. Jenkinson, electrical engineer, Rodborough, near Stroud, has been released.

The trustee (Mr. E. W. C. Whittaker, 3, Portland-street, Southampton) in the bankruptcy of Wm. Thos. Harris, electrical enigneer, 460 and 464, Commercial-road, and 47, Emanuel-street, Portsmouth, has been released.

The liquidator (Mr. H. de V. Brougham, 33, Carey-street, London W.C.) in the winding-up of Improved Electric Supplies (Ltd.), 7, Great Newport-street, London, W.C., has been released.

Bankruptcy Petition.—A bankruptcy petition against Morris Zains, electrical engineer, &c., 98 and 105, Wardour-street, London, W., will be heard on Oct. 6 at the London Bankruptcy Court.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked * are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. Names within parentheses are those of communicators of inventions. When complete Specification accompanies application, an asterisk is affixed.*

July 11, 1910.

16,478 THOMSON. Anchor insulator for metallic cable suspender.
16,485 LITTLER, jun. Quick-break switch or circuit-breaker.
16,486 PATON. Interlocking switch or fuse or gate-end box.
16,501 HILL. Electromagnetic friction clutch.
16,522 SERPEK. Electrical resistance furnaces. (Addition to No. 12,601/10.)*

July 12, 1910.

16,575 LEASON. Electric-lighting cable slip-plug connector for electrically-lighted trains.
16,626 DAVIES. Electromagnetic lock.

July 13, 1910.

16,763 KLEIN. Alternating current and alternating and direct-current machines.*

July 14, 1910.

16,796 HARDY. Double-pole sparking plugs for use chiefly with internal-combustion engines.
16,841 AUGUST SCHWARZ BOGENLAMPENFABRIK. Arc lamps for two or more pairs of electrodes. (Date applied for, 28/7/09.)*†
16,844 SIMMS & SIMMS MAGNETO CO. High-tension magneto-electric apparatus.

July 15, 1910.

16,904 LICHTENFELD. Switch devices for electric circuits.
16,933 SYKES, COOKE, JOHNSON & SYKES. Insulated rail-joints.

July 16, 1910.

16,947 ROMER. Intercommunication telephone systems and apparatus therefor.
16,997 SIEMENS SCHUCKERTWERKE G.M.B.H. Electric speed regulation of machines. (Date applied for, 17/7/09.)*†
17,010 ROSENBERG & PECK. Braking induction motors.

July 18, 1910.

17,047 SIEMENS-SCHUCKERTWERKE G.M.B.H. Electric fuses. (Addition to No. 14,622/08. Date applied for, 23/7/09.)*†
17,052 MERZ. Switches.
17,091 WESTON. Electrical measuring instruments.*
17,107 ADAMS MFG. CO. (Cutler Hammer Mfg. Co., U.S.) Controllers for electric motors.*
17,110 ADAMS MFG. CO. (Cutler Hammer Mfg. Co., U.S.) Electromechanical controlling-devices.*

July 19, 1910.

17,141 RICHARDSON. Gauge or indicator for denoting electrically any degree of vacuum or pressure or both.
17,148 MONRO. Conduits or casings for electric conductors.
17,156 ALLGEMEINE ELEKTRICITATS GES. Circuit-closing device for electric signalling devices. (Date applied for, 19/7/09.)*†
17,166 ADAMS MFG. CO. (Cutler Hammer Mfg. Co., U.S.) Starting devices for electric motors.*
17,177 B.T.-H. CO. & WHITCHER. Protective devices for electric distribution systems.

July 20, 1910.

17,227 KNUDSEN. Telegraphic apparatus.
17,235 SIEMENS BROS. DYNAMO WORKS. (Siemens Schuckertwerke G.m.b.H., Germany.) Means for working two motor controllers by a single operating handle or for like purposes.*
17,236 WATKINS. Device for grinding the contact surfaces of carbon brushes for dynamos or other purposes.
17,247 JAMES. Means for electrically-driving machines at variable speeds.
17,249 STIRK. Switchgear for controlling motor driven planing machines and the like.
17,278 B.T.-H. CO. (G.E. Co., U.S.) Electrodes for arc lighting.*

SPECIFICATIONS PUBLISHED.

1909 SPECIFICATIONS.

13,443 BERRY & MARKHAM. Protected or armour-clad electric switch fuses.
15,888 LEITNER. Automatic battery overcharge-preventer.
15,960 FLOOD. Electrolytic cell.
16,547 ROSS. Electric heaters.
16,630 AKT.-GES. BRCWN, BOVERI ET CIE. Regulation of electric installations. (Date applied for, 16/9/08.)
16,682 JACKSON. Trolley heads.
16,624 PROCTOR. Arc lamps.
18,624 VIRY. Devices for controlling movements from a distance. (Date applied for 14/8/08.)
18,934 EDWARDS. (Rosen.) Telegraph sending-machines.
20,587 LIVESAY. Electric generating systems.
20,780 JONES & NELSON. Actuating tramway rail points.
20,786 WALKER. Means for making and breaking electrical circuits or contracts.
22,827 PODSZUS. Vapour electric apparatus. (Date applied for, 7/10/08.)

COMPANIES' MEETINGS AND REPORTS.

ALLGEMEINE ELEKTRICITATS GESELLSCHAFT (BERLIN).—The directors' report for the year ended June 30 states that, after deduction of expenses, debenture interest and depreciation, 18,425,000 marks (£921,250) remains, compared with 16,385,000 marks (£819,250) in preceding year. The annual general meeting will be invited to approve a dividend of 14 per cent., compared with 13 per cent. for 1908-9. Besides the usual sums written off, 1,000,000 marks (£50,000) are to be added to general reserve and another 1,000,000 marks (£50,000) as special reserve to meet coupon tax. The turnover for the first two months of the current year, together with orders booked runs up to 247,000,000 marks (£12,350,000), compared with 214,000,000 marks (£10,700,000) for the corresponding period of 1909. The directors' and supervising committee's proposals concerning the Felten & Guilleaume-Lahmeyer Works Co. (THE ELECTRICIAN, Sept. 9, 1910) will be put before the meeting.

BRITISH THOMSON-HOUSTON CO. (LTD.).—The directors' report for the year ended March 31 states that the buildings and machinery have been maintained in first-class condition during the year. A number of improvements and additions have been made, the most important being an extension to the incandescent lamp factory costing £19,000, practically doubling its size and capacity, and an extension to the main factory (largely to take care of the increase in the turbine business) now approaching completion, costing approximately £30,000. Another building is being enlarged, the estimated cost being about £11,000. The turbine business continues to give satisfactory results, and many important orders have been executed during the year. The company has made further satisfactory progress in the development of metal filament (tungsten) lamps, and, to meet the increasing demand, has extended its manufacturing facilities. Following the example of the General Electric Co. of (New York), the company has adopted and registered "Mazda" as its trade mark for tungsten lamps. The company has exchanged licences with the Osram Lamp Works (Ltd.) on all its metal filament lamp patents. Under the terms of the trust deed securing the issue of the debentures, the company had to pay to the trustees on Feb. 28 last £3,339 to be applied by them in purchasing debentures in the market. Since the closing of the books debentures of the par value of £3,361 have been purchased, making the total par value of debentures retired to date £10,421. The directors have followed their usual practice of making reserves to cover risks in connection with bad debts, depreciation of shares held by the company and for other contingencies. There was a

Digitized by Google

profit of £10,932. 8s. 11d. as the result of the year's working, after paying interest on debentures and on loans. The appropriation of this sum is mainly to depreciations, and £248. 0s. 10d. is carried forward, making with previous year's balance, £2,599. 3s. 9d.

DICK, KERR & CO. (LTD.)—The profits earned during the 12 months' trading to June 30 amounted to £22,820. 19s. 2d. Debenture interest, trustees' fees and the sum required to provide for premium payable on redemption of the debenture stock have been met, and absorb £12,404. 8s. 7d., leaving £10,416. 10s. 7d., added to £63,141. 10s. 1d. brought forward, making £73,558. 0s. 8d. available for appropriation. Preference dividend requires £18,300, a dividend of 5 per cent. on the ordinary shares (less tax) £13,000, and the carry forward £42,258. 0s. 8d. The severe competition referred to in the last report has continued throughout the past year. The directors refer with regret to the death of their friend and colleague, Mr. George Flett, the managing director. Mr. Walter Rutherford, who was assistant managing director, has been appointed to the position.

MANILA ELECTRIC RAILROAD & LIGHTING CORPN.—Of the many American enterprises which have sprung up in Manila since the annexation of the Philippines by the United States this corporation is one of the most important. It was incorporated in 1903 and has an issued capital of $5,000,000 with a bonded debt of $5,512,000, and owns the entire stock and bonds of the Manila Electric Railroad & Light Co., all the capital stock of the Manila Suburban Railways Co., and more than 98 per cent. of the capital stock of La Electricista, a Spanish company conducting an electric lighting business in Manila. The Manila Electric Railroad & Light Co. is the ower of a 50-year franchise granted in March, 1903, by the municipality of Manila, and operates all the electric railways in Manila, in which city it is also authorised to carry on a general electric lighting business. The Manila Suburban Railway has a 47-year franchise from January, 1906, and its lines are a part of the system of the Manila Electric Railroad & Light Co. providing connecting links to the suburbs with that company's system. Manila, which is the social, political and business centre of the Philippines, has a population of about 300,000, and transacts about 80 per cent. of the entire commerce of the Archipelago. As regards the earnings of the company, statistics show that while profits fell off slightly in the first half of 1909, owing to a strike which was successfully overcome after lasting a considerable time, they recovered substantially in the corresponding period of the current year, and amounted to $313,277 against $242,046 in 1909, and $262,045 in 1908, and the company has increased its surplus from $342,492 as at Dec. 31, 1907, to $433,374 at Dec. 31, 1909. The corporation paid 3 per cent. on its common stock for 1906 and 1907, and 4 per cent. for each of its following years. During 1910 a distribution of 1 per cent. per quarter has been made. The price of the stock has risen within the past three months from $59.50 to $65 ex div. This latter figure yields to the investor on the present dividend £6. 3s. per cent.

UNDERGROUND ELECTRIC RAILWAYS CO. OF LONDON (LTD.)—At the meeting on Wednesday Sir Edgar Speyer, who moved the adoption of the report, said he was glad to be able to record results which, although not yet satisfactory, were considerably better than was anticipated several years ago. The dividends paid on the share capital of the railway companies concerned did not yet represent anything like a fair and adequate return on the large amount invested in those enterprises. Administration expenses showed a saving of over £4,000. The increase in income from the operation of the power house was due to £3,000 interest on increased expenditure (of which £2,500 referred to the period ended Dec. 31 last), and the balance of £1,700 represented additional profit. The income from investments increased by nearly £13,000, due not so much to an expansion of traffic receipts as to a reduction in working expenses of the London Electric Railway Co. The decrease in costs had been brought about almost entirely by a reduction in the price paid for electric current. The traffic could not, in the nature of things, grow in the same quick manner, and they must look forward to a somewhat smaller expansion of earnings than was the case during the first two or three years after the railways were opened. The Charing Cross line had to contend with the competition of the London County Council tramways, which, together with a reduction in fares on the railway, forced upon the company by the low fares inaugurated by the L.C.C., had resulted in a decrease of traffic receipts during the half-year under review. The London Electric Railway Co. was asking Parliament for fresh powers to build the Charing Cross extension on modified plans. The amalgamation of the three tube railways should result in economies in working and in higher credit.

UNITED ELECTRIC CAR CO. (LTD.)—At the meeting on Wednesday Mr. Geo. Richardson said the result of the past year's working had been most satisfactory in view of the continual slackness of the works and the small output, although the company had received a good share of the work which had been given out and which was worth having during the year. The net profit, after allowing for depreciation, debenture interest, &c., was £8,478, or about £400 less than the previous year. The balance to be disposed of amounted to £10,811, and the directors considered themselves justified in declaring a dividend of 2½ per cent. on the ordinary shares. He was glad to see signs that their reputation for good work was extending, and had become established both at home and abroad. That was borne out by repeat orders received, as well as small orders not previously solicited. The directors were hopeful that English corporations and others would soon again be in the market, as many of the cars in use had now been running eight or 10 years, and the directors did not think that large corporations, as a rule, would find it convenient or advisable to build their own. There was no immediate sign of any improvement, but the directors were doing all they could to secure orders

NEW COMPANIES, STATUTORY RETURNS, MORTGAGES AND CHARGES.

NEW COMPANIES.

INSTITUTE OF METALS.—This institute was registered on Sept. 10, and the word "Limited" is omitted from the title by licence of the Board of Trade. There are 1,000 members, each liable for £1 in the event of winding-up. The objects are to take over all or any of the assets and liabilities of the unincorporated society known as the Institute of Metals, and to adopt an agreement with G. Shaw Scott. The management is vested in a Council.

NUNEATON ELECTRICAL CONTRACTING CO. (LTD.) (111,703.)—Reg. Sept. 12, capital £1,000 in £1 shares, to carry on in Nuneaton or elsewhere the business of dealers in electrical fittings and appliances, electrical engineers, &c. Private company. First directors, F. Frankland and G. Cross. Reg. office, Abbey Gate, Nuneaton.

STATUTORY RETURN.

CROMPTON & CO. (LTD.)—Return to Aug. 11 gives capital as £300,000 in £3 shares. 85,000 shares taken up, £3 per share called up, and £249,000 paid. £6,000 considered as paid on 2,000 shares. Mortgages and charges, £175,000.

MORTGAGES AND CHARGES.

CHURCH STRETTON ELECTRIC SUPPLY CO. (LTD.)—Further charge on freehold hereditaments at Church Stretton, dated Sept. 9, to secure £120. Holder, E. Bond.

FOSTER ARC LAMP & ENG. CO. (LTD.)—Charge on certain land, &c., in Morden-road, Merton, dated Sept. 2, 1910, to secure all moneys due or to become due from company to London County & Westminster Bank.

CITY NOTES.

MEMORANDA (Sept. 22).—**Bank rate 3 per cent. (since June 9, 1910). Price of silver,** 24⅞d. per oz. Consols 80¼—80½ for money; 80⅝—80⅞ for account. **Consols** Pay Day, Oct. 5; **Stock and Shares Continuation Days,** Sept. 27 and Oct. 12; **Ticket Days,** Sept. 28 and Oct. 13; **Pay Days,** Sept. 29 and Oct. 14; **Mining Shares Carry Over Day,** Sept. 26.

PRICES OF METALS (London).—*Copper*, cash, 54⅛; three months, 53½. *Lead*, English, 12⅛—13½; foreign, 12⅛—12⅞. *Spelter*, 23½—23½. *Tin*, English, 155—156; foreign cash, 155⅜; three months, 155½. *Iron*, Cleveland, cash, 49/1, three months, 49/11.

CHADBURN'S (SHIP) TELEGRAPH CO. (LTD.)—The directors have declared a dividend on the preference shares of 6 per cent. per annum (less tax) for the half-year ended 30th inst.

CITY OF CARLISLE ELECTRIC TRAMWAYS CO. (LTD.)—Messrs. Balfour, Beatty & Co. have acquired a controlling financial interest in this company, and it is proposed to extend and improve the system.

DUNDEE, BROUGHTY FERRY & DISTRICT TRAMWAYS CO. (LTD.)—The directors' report for the year ended July 31 states that the profit (including sum brought forward), after providing for interest, amounts to £5,070. The directors propose to pay a dividend on the ordinary shares of 2 per cent. for the year (£574), carrying forward £296.

EASTERN EXTENSION AUSTRALASIA & CHINA TELEGRAPH CO. (LTD.) The directors have declared an interim dividend for the quarter ended June 30 last of 2s. 6d. per share (tax free), payable on Oct. 15. The share register will be closed from 7th to 14th prox. inclusive.

FOLKESTONE ELECTRICITY SUPPLY CO. (L'D.)—The directors have declared an interim dividend at the rate of 4 per cent. (2s. per share), less tax, on the ordinary shares for the past half-year.

KALGOORLIE ELECTRIC POWER & LIGHTING CORPN. (LTD.)—The directors have declared a dividend on the preference shares at the rate of 6 per cent. per annum for the six months to Sept. 30.

MADRAS ELECTRIC TRAMWAYS (1904) (LTD.)—The directors have declared an interim dividend at the rate of 4½ per cent. (2s. 3d. per share) less tax, on the preferred ordinary shares for the past half-year, payable 30th inst.

PERTH (W.A.) ELECTRIC TRAMWAYS (LTD.)—This company announce that the recent strike of their motormen and conductors has come to an end, and the directors have received a cablegram from the manager that there would be no more trouble.

SAO PAULO TRAMWAY, LIGHT & POWER CO. (LTD.)—A quarterly dividend of 2½ per cent. is announced.

SHAWINIGAN WATER & POWER CO.—A quarterly dividend of 1 per cent. has been declared.

SIR W. G. ARMSTRONG, WHITWORTH & CO. (LTD.)—An interim dividend is announced at the rate of 10 per cent. per annum on the ordinary (tax free) and 4 per cent. on the preference shares, less tax.

WESTERN ELECTRIC CO. (LTD.)—Mr. J. E. Kingsbury, formerly general manager in London of the Western Electric Co., has joined the board of directors of the Western Electric Co. (Ltd.).

WESTERN UNION TELEGRAPH CO.—The directors have declared a quarterly dividend of ¾ per cent. The net quarterly earnings (partly estimated) amount to $2,000,000, an increase of $71,000, and the surplus amounts to $819,000

NOW READY

Bound Half Calf, **25s.**

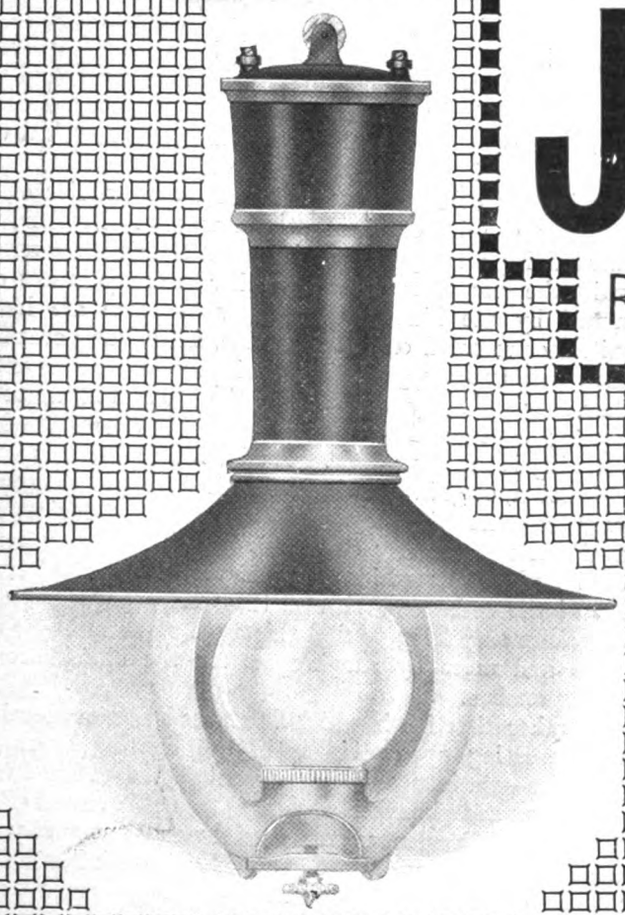
Electric Traction on Railways

BY PHILIP DAWSON.

Over **1,000** pages, **600** Illus.

PROSPECTUS FREE ON APPLICATION.

"The Electrician" Printing & Publishing Co., Ltd.,
1, 2 and 3, Salisbury Court, Fleet Street, London.



JANDUS

REGENERATIVE ARC LAMP.

8,000

in use.

Lowest Carbon Costs—80 hours life per pair.

Most Effective Horizontal Distribution.

500 and 250 watt patterns are now ready.

50 per cent. more light than an ordinary flame arc, SIX TIMES AS EFFICIENT AS METALLIC FILAMENT LAMPS, and absolutely steady.

Flame Arc Lamp Progress.

WE have again to report substantial progress in flame arc lamp development during the past 12 months. Such a statement may seem exaggerated to such as are confirmed pessimists, among whom we are sometimes classed, and to those who, lacking perspective, see too clearly the happenings of the past few months—a state of mind which is known in some circles as a "pitiful continuation of irritation." We would ask electrical engineers and contractors not to take too seriously the result of the competitive tenders between the gas and electric lighting authorities in Westminster. It has already been amply shown that matters quite apart from the relative efficiency of the two illuminants were determining factors, while even the results published do not indicate that overwhelming superiority in favour of gas which some would have us believe.

A man who continually reads journals of one political colour cannot help becoming partisan. The obvious way to prevent this is to study both sides of the question; even then the issue is complicated by the introduction of matter quite irrelevant to the subject. If we are to believe our gas contemporaries, flame arc lighting must hide its diminished head when compared with high-pressure gas, and take its place along with such "back numbers" as the bat's-wing burner. But, it should be noted, while electrical papers freely publish figures relating to the consumption, candle-power and efficiency of flame arc lamps, similar figures dealing with high-pressure gas lamps are singularly absent from the columns of our contemporaries, and must generally be obtained from independent sources. Instead, we are treated to bald "statements of facts," or results are given without those intermediate steps which would make the argument intelligible to us. When one thing is vastly superior to others it is generally found that unquestionable proofs of this superiority are forthcoming from its supporters. We should like our gas contemporaries to give us in full detail the *cost* of illuminant and of running and maintaining one of those famous 3,000 c.p. lamps which we hear so much about.

As a matter of fact, except in London's streets, where, as already pointed out, the issue has been confounded in a number of ways, flame arc lighting has made steady progress. The number of shopkeepers who are employing this form of illumination has been, and is gradually increasing. This seems at first sight peculiar; for a shopkeeper should above all things have a commercial mind. Yet apparently thousands of this class of citizen are using what we are told is an inferior form of lighting, and have even complained in certain cases when this unsatisfactory type of illuminant has been temporarily superseded in the streets in which they carry on their business.

As a matter of fact, flame arc lighting is eminently suitable for shop lighting, which is perhaps why shopkeepers use it. The colour of the light allows materials to be matched with the same facility as in the daytime, while a general and good illumination of both the interior and the exterior of the premises can be obtained at a low cost. Further, the surrounding atmosphere is not heated to any great extent, while the oxygen required for other purposes is not consumed by the illuminant. A row of flame arc lamps, suitably protected on the road side, when hung outside a shop shows up the goods in the window to such an extent that they are easily visible from the top and inside of the passing 'buses, and thus an increase in the range of advertising is made possible. Again, if long-burning lamps are chosen, even in the winter months they will not require very frequent trimming, while the dust-free devices now available prevent any obscuration of the globe, and thus the illumination remains the same throughout the burning life of the carbons. With all these advantages it is not, therefore, surprising to find this type of lamp being used more and more by shopkeepers for the illumination of their premises.

Another direction in which flame arc lamps are receiving an increasing application is in the lighting of railway premises—stations and goods yards. We rather expect this sentence to be received with shouts of "Victoria," and may, in anticipation, express a mild wonderment why such a go-ahead railway as the London, Brighton & South Coast should have so far fallen from grace in this respect as to employ a second-rate illuminant at a number of its large stations when, both from theoretical and practical data, flame arc lamps are more suitable for the purpose. In a railway goods yard a fair general light is the chief desideratum—sufficient illumination to render the trucks visible without that amount of glare which makes work near moving vehicles dangerous. A few high-power flame arc lamps placed well above the ground level admirably fulfil this condition. As an example of this class of work we may quote the Paddington goods station of the Great Western Railway. A light of 3,000 c.p. can now be produced at the same cost as 300 c.p. in former days. Thus illumination of large areas can be carried out with a proportionate reduction in capital cost and in the charges for current. The same arguments apply to the lighting of passenger stations, where a good general illumination can be obtained by suspending a few lamps from the roof. Paddington and Charing Cross passenger stations are examples of this class of work.

Digitized by Google

In factories, again, much progress has been made, and it is in these cases that well-thought-out schemes of combined lighting have an advantage. General lighting can be efficiently provided by flame arc lamps, while each tool or bench may be fitted with its own adjustable metal filament lamp, the light from which may be thrown just where it is required. Mention should be made in this connection of the benefits obtainable in factories by the use for general lighting of mercury vapour lamps. The absence of red rays in the light from these lamps does not matter in such a case, while they give a restful light which is eminently suitable for the work performed.

We may, therefore, say that good progress has been made during the past 12 months in the use of flame arc lamps for a variety of purposes. Their use, or rather the use of electric lighting, is recommended by H.M. Inspectors for factory work, as "not seldom is it found that the necessity for artificial light is the excuse put forward for an unreasonably high and a vitiated atmosphere." It will, therefore, be seen that it is recognised, in some circles, at any rate, that the use of gas for lighting leads to a contamination of the atmosphere which would be avoided were electricity employed.

As will be seen from a perusal of the columns of this issue, there is ample example to encourage manufacturers, shopkeepers and street authorities to employ flame arc lamps for illuminating purposes. By so doing they will obtain a cheap and efficient light, easy to upkeep, requiring no skilled attendance, economical to maintain and in every way fit for their purpose.

Gushem's Gas Arcs.*

DRAMATIS PERSONÆ.

Mr. H. S. GUSHEM, *a successful draper, but weak on the point of safety of his premises and his employees.*
Mr. T. GASCHWANK, *a pushful gasman.*
Mr. J. P. PHILPOCK, *an enterprising insurance agent.*
FOREMAN.
WORKMAN.
MATE.
Mrs. GASCHWANK, SHOPWALKER, CLERK, SHOP ASSISTANTS.

ACT. I.

SCENE. *Gushem's Emporium. Gushem's Office. Mr. H. S. Gushem seated at his desk. Time,* 10 *a.m.* (*any morning*). *Enter clerk with card.*

Clerk. Gentleman to see you, Sir.

Gushem (*reading card*). Theodore Gaschwank, Canvasser-in-Chief Risington Gas Corporation. (*To clerk*) What does he want?

Clerk. He said his card explained everything, sir!

Gushem. Let him cool his heels a bit, then let him in. Carefully, mind—in ten minutes.

Exit Clerk.

Gushem. Gas! Whew! Fancy I can smell it already. And this after using electric light for ten years. (*Goes to letter file, takes out letter, and reads.*)

Dear Sir: Why do you continue using electric light when gas is ten times cheaper? Do you know, sir, that we will replace your existing inefficient shop lights with modern gas arcs—inside and outside the shop—absolutely free of charge? This remarkable proposal must appeal to you as a business man. Our Mr. Theodore Gaschwank will call on you to-morrow morning to give you full details and to obtain your consent to the suggested alteration.

Sits down after laying letter before him.

Enter clerk, followed by Mr. T. Gaschwank.

Clerk. Mr. Theodore Gaschwank.

Gushem waves him to a chair.

Gush. Now, sir, I can spare you very little time. I am busy.

Gas. I see you have our letter. Our plan is simplicity itself. Gas burned in inverted burners placed in a suitable lantern can make electricity look sick anyway.

Gush. You notice we are lighted throughout with electric light.

Gas. More fool you!

Gush. Mr. Gaschwank, sir, how dare you?

Gas. I'll dare anything. Aren't you a fool to pay ten times more than you need for your light? Why, my dear sir, you are just casting your golden quids before greedy electric light shareholders, and they don't appreciate it a bit. What's more, you know it.

Gush. Your manners are most offensive, but with regard to the electric light companies, I must admit that you are not altogether in the wrong.

Gas. Of course I am not. They take your money and glad to do it. But otherwise they look upon you as an unmitigated nuisance. Your use of electric light shows you have an unbusiness like mind.

Gush. Indeed, sir, and will you kindly leave me to judge of my own affairs.

Gas. Gas is ten times the cheaper, and you can't get away from it.

Gush. I don't think so. But anyway, price is not everything.

Gas. Look at our offer again. (*Takes up letter and reads.*) "We will replace your existing inefficient shop lights with modern gas arcs."

Gush. Gas doesn't arc!

Gas. Figure of speech, my dear sir.

Gush. Conveniently so. No electric light man talks about "an electric mantle." If you can't be original, don't copy.

Gas. Well, sir, I will shortly put before you the advantages which we claim for gas. And we are quite right in claiming them. We are driving electric light out on every side. It will soon be as much a back number as the horse 'bus. And why? Gas is cheaper, cleaner, cooler and gives a better light.

Gush. I don't believe all that. But I will give you gas people the credit for one thing: You know how to push your wares, and I am not at all sure that you don't really believe all you say. What you said about the electric light companies was not far wrong. They are too lackadaisical; and would certainly never think of sending a representative to invade a business man's sanctum at this hour in the morning. I repeat I don't believe all you say, but, as a sportsman, I am a good mind to accept your offer and hang the consequences.

Gas. Isn't it a good proposal?

Gush. (*rising*). Yes sir, it is, and damme, sir, you're going to carry it through, whether you like it or not. (*Stands over Gaschwank, who begins to squirm.*) Now, sir (*banging letter on the table*), you will keep to the terms of this arrangement?

Gas. Well, of course, that's what I'm here for.

Gush. Well, in that case, I'll put in your gas arcs and see whether your deeds are as magnificent as your words. You'd better set to work at once, before I repent.

Gas. This is just bully.

Gush. I am glad you think so. Well, hurry up! Bring the agreement round here this afternoon for signature and complete the change over within next week. To-day is Thursday.

Gas. (*aside*). Isn't he just a peach. I'll make some capital out of this. (*To Gushem.*) Good-day, sir, our secretary will bring you the agreement this afternoon at four o'clock.

Gush. Shall be out then. Tell him to come at three.

Exit Gaschwank with a nod.

Gush. Well, I'm sure I don't know whether I've done the best thing. But, at any rate, I shall be able to test for myself whether there's anything in these wonderful claims that Gaschwank makes. And it's the best time of year for testing, too, with the Christmas season coming on. We shall be able to see whether the shops really are any cooler when gas is used. They were hot enough last year, with flame arcs, in all conscience.

Enter clerk. Presents card.

Gush. Hallo! What's he want? More expense, I suppose. Show him in.

Enter Philpock.

Gush. What do you want? I sent you a cheque for your premium last week.

Philpock. I know that, my dear Mr. Gushem, but news travels fast.

Gush. What news?

Phil. You are putting in gas.

Gush. Certainly.

Phil. And you are prepared to meet the larger premium which the greater—I might say infinitely greater—risk entails?

Gush. Well, Gaschwank says not. But anyhow, I suppose your idea is always to make a bit when you can—like everyone else. How much do you want?

Phil. I'm afraid we shall have to double your premium. There is a greater risk, you see; our statistics show it.

Gush. Statistics will show anything, even that calico's silk. There's no help for it, I suppose. I'm not going to risk my buildings, and even with this extra cost gas will be cheaper than electric light on Gaschwank's showing.

Writes cheque.

Phil. Yes; but it costs them more. Gaschwank's idea is to get hold of a few big shops like yours, offer them a cut price and use them as an advertisement. They can't really sell at that price.

Gush. Well, anyhow, the thing's done now. I can't back out. Here goes. Have a drink, Philpock. (*Whisky, siphons and glasses are produced, and the votive operations usual to the occasion duly performed behind a large screen*).

Gush. Well, you must excuse me now, I am busy. (*Exit Philpock. Gushem settles himself down at his desk. 'Phone bell rings.*)

Gush. Hello! The Fire Brigade office? Oh, yes. What, Mr. McWash? Morning. What's that. Hear I've decided to put in gas arcs and want to know if—(*Curtain is here seen slowly descending*)—you can have a few more——oh, confound it all! (*Bangs receiver on hook, and as the curtain falls Gushem is last seen staring at the telephone with a look of great disgust on his face.*)

End Act I.

Act II.

Scene I. *Outside Gushem's shop. Workman busy with step ladders. A high wind blowing. On right, workman on ladder working at "gas arc." His mate below.*

First Workman. Gimme them mantles.

Mate. Orright, cockey, wot's the 'urry?

Workman. Naa then, look lively.

Mate (*mounting steps*). Keep yer 'air on, wiskers. Don't be so frisky.

Workman (*reaching down and snatching box*). Wy doncher 'urry? Look at the time.

Small crowd gathers.

Mate. Get awiy you boys. (*Workman opens box and extracts inverted mantle carefully, but high wind blows it out of his hand. Great scramble among small boys for the support on which the mantle had been.*)

Workman (*looking daggers*). Drat the wind. (*Takes out another mantle and shields with his body while he reaches out to the lantern. Wind gust shakes the steps and mantle is broken against side of glass. Workman throws the support down with an oath on to heads of small boys.*)

Workman (*to his mate*). 'Old the steps, can't ye. Ye young cub. That's two gone. Drat the wind. (*Turns round on the steps and another wind gust makes him clutch at the mantle box, which comes away in his hands, and workman falls backwards with box in his extended arms on to the pavement. Workman gets up, kicks box of mantles in his disgust, and then chases and cuffs his mate.*)

Enter Foreman.

Foreman. What's this hullabulloo?

Workman. It's this 'ere infernal wind. Me an' my mate 'as bin tryin' to get these mantles on, but the wind blows them an' us all over the place. Don't it matey?

Brief consultation, after which Workman and Foreman exit.

Mate. These 'ere bloomin' mantles, they're allus a blowin' away or blowin' off or summut like that. I shawn't be 'arf glad when I starts wiv the Electric Company. (*Soliloquising.*) Yer kno', between you and me, these 'ere diverted mantles is no good. Look at to-day. 'Ow are we a-goin ter get 'em on those lanterns wi' this 'ere wind. W'en Bill ses d— the wind, I ses 'ere, 'ere! becos it means another mantle busted. (*Taking the audience into his confidence.*)

REGD TRADE MARK

It's Wonderfully Simple.

'Ave yer ever tried litin' these mantles in yer 'and. I'll jes' show ye, just ter demonstrate 'ow them advertisements is all lies. Yer know these pikshers on the 'ordings—Servant girls a-trying to 'it the mantles off the 'ooks and breaking everything except th' mantles. Ladies and gentlemen, as the cheap jack ses, it's all kid. Lemme show yer. (*Takes new mantle, mounts steps, carefully strikes match and fires the mantle.*) That comes of smokin' Woodbines. I can allus lite up in a wind. Naa then, ladies and gentlemen, I 'old in my 'and the 'ead of a 'ard and 'orny beetle, as the perfessor ses. (*Waves mantle, which is puffed away into dust by the wind.*) There you are. You see they're not as strong as some would like to make out. I tell you they're an awful job to get on, even on a quiet day, and when they are up it's ten to one they'll bust almost directly they're lighted. The 'ole thing's a blooming swindle, and what's more they're losing by it. I'm leaving before I get the sack, as they're turning off men somethin' awful. Well, any'ow, I'll soon be out of it now. Thank goodness! 'Ello, 'ere they come!

Re-enter Foreman and Workman, smacking their lips.

Workman. I think the screen will do it; it'll keep off the wind while the mantles are bein' put on.

Foreman. Yes, get it up at once, and do hurry with the rest of the lanterns. We shan't be alight to-morrow night if you go on at this pace. *Exit.*

Workman. Naa then, matey, get that 'ere screen out and we'll 'ave these mantles on in no time.

Large screen is brought out from truck and wind proceeds to play havoc with it. Assistance is brought and with some difficulty the screen is placed round the lantern. More mantles are brought, and the curtain descends on Workman triumphantly placing the first mantle in position.

SCENE II. *Another view of Gushem's office, through door and glass screen of which can be seen the long drapery counter. Time, 8 p.m. Monday in Christmas week. Shop brilliantly lighted by "gas arcs." One of these hangs in centre of Gushem's office. Gushem discovered at his desk, writing with his coat and vest off and frequently mopping his brow.*

Gush. By Jove! Snow and frost outside and the temperature in here up to summer heat. By the look of the shop, though, we are doing well. We can't get 'em away fast enough. *Answers telephone. Enter Gaschwank, who helps himself to a cigar from a box on the table.*

Gush. (*turning round in his chair*). No smoking allowed, sir. Ah, of course, I forgot we altered the rule when gas was put in.

Gas. Say, now, sirree, I guess your store looks just top hole.

Disturbance in shop. Assistants rushing hither and thither. Group seen approaching Gushem's office. Enter clerk.

Clerk. Lady fainted sir, they're bringing her in here.

Gush. (*leaving telephone*). In here. Why in here?

Crowd round office door pushes in and lady is laid on a couch. Gaschwank stoops over the prostrate figure.

Gas. Skiooka! (*Aside.*) My wife! (*Hurriedly leaves through door.*)

Gush. Let's have some air. Boy, get a hook and pull down that window at the top. Never mind the snow. Ask the telephone girl to ring for a doctor. (*Turning to group.*) Poor thing! What's the trouble do you think?

Shopwalker. The heat, sir. It's just terrible in the shop. People are crowding in and they get so baked they've got no strength to get out. I wish you 'adn't put in these gas arcs.

.td.,

DUBLIN—16, St. Andrew Street.
BELFAST—13, Queen Street.
BRISTOL—2, Bristol Bridge.

Gush. Silence, sir, that's my business.

High wind blows across the office through open window and blows out the gas arc in the centre. Office remains lighted from shop through glass screen. Gushem seen rushing about.

Gushem (shouting). I knew it! I might have guessed it; no weather proof lanterns on these inside lamps. Boy! Boy! Bring that lamp hook. We'll have the place full of gas in no time.

Boy, in his hurry, breaks glass screen with the lamp hook and several panels fall out. Gushem rushes at the boy, snatches the hook from him and breaks another panel in his hurry. He reaches up to the extinguished lantern and endeavours vainly to pull the chain controlling the tap.

Shopwalker. Hurry up, sir. The gas is escaping and ther'll be an explosion in a minute.

In the excitement no one thinks of shutting the window, and the draught blows through the broken glass panes into the drapery department. Just outside is an ordinary gas mantle fitted with chimney and fixed on a bracket. The escaping gas is seen to flare over this chimney and ignite with a flop a quantity of curtains near by. This is instantly noticed by a section of the crowd in the shop who immediately begin to crowd together in an alarming fashion and try their best to get out into the open air.

Gush. (who has not noticed the fire). At last, though I ought not to have pulled that chain so hard; it's broken off, but the gas can't come out now. *(Turns and looks into shop.)* Good heavens! Oh, my hat. Where's that poor lady. Here you, shut that window! We're in for it now. Gaschwank! Where's that bounder?

Rushes to telephone.

Gush. (frantically, with receiver first to his mouth, then to his ear). FIRE!

Curtain descends for some seconds, then rises again to discover Gushem's office in ruins and fire brigade in possession of drapery department. In the distance can be seen ambulances at work. On the right, party bears off the still prostrate figure of Mrs. Gaschwank.

Gush., holding his head and wringing his hands alternately, is led off by fireman, and is heard muttering "Gaschwank Gaschwank."

CURTAIN.

The MSS. of the foregoing tragedy has reached us from a reliable source and is accompanied by the following cutting from the "Risington Trumpeter," which will doubtless not be without interest to our readers.

FIRE AT GUSHEM'S.

The drapery department of Messrs. Gushem (Ltd.), The Emporium, Broad-street, was, we regret to announce, entirely burned out during the early part of last evening. The shop was crowded at the time of the outbreak, but happily the emergency exits allowed of the public leaving the building with great ease, and fortunately the disaster was not increased by any loss of life. Several ladies were, however, trodden on during the rush, but after medical attention were able to proceed to their homes. The cause of the fire should, we understand, be attributed to the fusing of an electric wire in Mr. Gushem's office.

THE ELECTRICIAN INDUSTRIAL SUPPLEMENT
ISSUED MONTHLY with "THE ELECTRICIAN"
Telegraphic Address "ELECTRICIAN NEWSPAPER LONDON" Telephone No. 949 HOLBORN

All communications should be addressed to the Editor, "The Electrician" Industrial Supplement, 1, 2 and 3, Salisbury Court, Fleet Street, London, E.C.

Manufacturers, Contractors, Central Station Engineers, and those interested in Electrical Industrial Developments are cordially invited to contribute original matter to the SUPPLEMENT, and when suitable this will be inserted as space permits.

Filing Case for "The Electrician" Industrial Supplement.

The INDUSTRIAL SUPPLEMENT is holed for filing, and we are distributing cases which will hold twelve issues. On request a case will be sent to Consulting, Manufacturing, or Contracting firms; to Chief or Resident Engineers of Electricity Supply, Traction or Power Stations; to any firm of Merchants or Agents; to Railway, Tramway, Dock, Harbour, or other companies interested in the applications of Electric Power, &c., to their undertakings; and to other large consumers of electrical energy, either at home, in the Colonies, or abroad.

A portion of each issue of the SUPPLEMENT is reserved for special circulation oversea.

Editorial.

Engine-Room Illumination.

With the lighting season imminent, much is heard at this time of year about the way in which certain particular types of areas should be illuminated. Engineers know just which is the best way to light, say, a shop, a street or a factory (although this way is not always employed), but there are certain other places where the methods adopted are to some extent, even now, experimental, and among these are engine rooms. This does not imply that engine rooms are always badly lighted, but too often the method of simply putting in a few candle-power without considering what that candle-power is to do is followed,

An engine room is essentially a place where one should be able to see well at the darkest time of day or night The switchboard, for instance, should be well illuminated, so that the switches can be easily handled and the instruments easily read. This, of course, predicates an absence of glare, and the best way to carry out the work is doubtless to place the lamps on brackets sprouting from the top of the board and carefully shaded on the outer side. The provision of plugs and sockets to which portable lamps may be attached should not be forgotten, as this precaution does much to lighten the work of the attendant in his peregrinations behind the board. But, after all, the switchboard is only a part of the engine room, and it is to the lighting of the other and greater portion that we wish to call attention.

It would seem only natural that in designing the lighting of an engine room the possibility of having to do repairs or removals at night should have been considered. But in too many cases this possibility appears to have been altogether forgotten, and machinery parts, such as main bearings, governing gear and brushes, left in a gloom, which requires other means than the general lighting of the engine room for its dispersal.

It is satisfactory to the worker on plant, especially if this be in motion, when he is provided automatically, as it were, with sufficient lighting for his job without it being necessary for him to employ continually portable lamps and other similar apparatus, which at best is much in his way.

More attention might, therefore, be paid to the lighting of engine rooms, keeping these points in mind. High candle-power metal filament lamps suspended from the roof girders are excellent for this purpose, or if something more ambitious is desired, flame arc lamps may be used. These, if suspended at a sufficiently great height, give a very good general lighting with a small expenditure of energy. In considering this question of engine-room illumination the benefits derived from the use of reflectors and by having the walls of the engine room the proper colour should not be overlooked. White tiling, though expensive, is of course excellent from the reflective point of view, and where this method is used the same intensity of illumination may be obtained with many fewer lamps than when dull painted walls are employed. In the same way with reflectors; the light is, in general, required on the floor of the engine room, so that means for throwing down the rays are both useful and efficient. In cases where a travelling crane is used, means should be provided for hauling up the lamps out of reach when required. In this way the lamps can generally be burnt at the most efficient height, and only need be moved out of the way for the crane to pass. These are a few of the problems which must be solved before the engine room can be said to be properly lighted, and in thus searching for the best way to illuminate these places opportunity may also be taken to carry out experiments, the results of which will doubtless be useful when it is required to light halls and other similar areas in the most satisfactory way.

Electricity and the Cinematograph.

At the present time both theatrical and music hall enterprises are being hard hit by the erection of cinematograph palaces. It is an ill wind that blows nobody good, and these "electric theatres" offer excellent ground for the operations of an enterprising electricity supply undertaking. This is certainly one of the cases where gas cannot be used, in spite of its "safety," but even so there is no reason why the prices for electrical energy should be raised unduly, as these places, both directly and indirectly, advertise the benefits of electric lighting. It may be argued that the load they afford is small and peaky, so that they are not entitled to any particular preference. But this is not altogether the case. Most of these "theatres" open at an early hour in the afternoon and continue until late in the evening, so that what peak there is is spread over a fairly long period, while the cinematograph arcs are by no means the whole load from these places, a very steady demand being made during the dark hours by the signs and other exterior lighting by which they are lavishly decorated. Even if the shows are too ephemeral in character to warrant large capital outlay, surely it is worth the risk on account of the advertisement obtained.

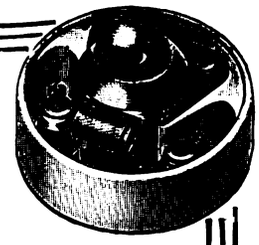
Satisfactory earthing
is ensured by use of



THE "KALKOS" SWITCH

¶ It ensures automatic and sure earthing of the dolly.

¶ It is absolutely watertight without the knob being enclosed.

¶ It is suitable for BOTH the "Kalkos" tinned tube and the "Sun" screwed steel conduit systems.

THE SUN ELECTRICAL CO., LTD.,

118-120, CHARING CROSS ROAD, LONDON, W.

Telegrams—"SECABILIS LONDON." Telephones—GERRARD **2291** and **2292.**

The blaze of electric light outside, the easy working of the machinery inside, and the coolness of the internal atmosphere, all help to draw attention to the advantages of electric lighting, not only for cinematograph theatres, but also for domestic purposes. An advertisement which costs nothing, and may even show a profit, is worth having.

Two Complaints.

It has often been our unpleasant duty to complain of the slow progress which the use of electrical energy is making for domestic purposes. In so doing we have tried to keep even the scales of argument and to apportion in a judicial way praise and blame on the two sections—manufacturer and supplier—whose business it is jointly to bring the advantages of electrical apparatus before the public.

The manufacturer considers that his business is done when the finished article is on view in the show-rooms; it is then that the seller and canvasser must step in; and persuade, wheedle or otherwise induce the public to purchase. In fact, he laments that the seller and canvasser do not take their responsibilities seriously enough. The public do not use electrical apparatus, he says, simply because they do not know there is electrical apparatus to use; and the unsatisfactory state of the business is due alone to slackness on the selling side.

On the other hand, the seller points out that it is difficult to sell apparatus which is flimsy, badly constructed and totally unsuited for the work it is supposed to do. He says that, if the manufacturer would supply him with a strong article which looked as if it had been designed to be used by the ordinary female cook instead of by a laboratory professor, he might have less difficulty in persuading the ladies resident in his area of operations that electrical cooking is really a good thing; and the *one* way of preventing the horrible smell and heat which seem inseparable from all other methods now in use. Our seller complains that before much can be done the manufacturer must recognise that the proper way to remove a plug from its socket is to pull on the "flex," and must design his apparatus accordingly. He must provide a kettle which, destitute of water, will not burn out when left in circuit. In fact, his domestic apparatus must no longer have as its chief characteristics flimsiness, bad workmanship and a tendency to go wrong on every conceivable occasion.

How are we to judge between so much conflicting evidence? Doubtless excuses and refutations are to be found for the details of both these complaints. But, to the unbiassed observer, it will be evident that neither side is wholly wrong in what it alleges concerning the other. It is a case of stalemate or "dishonours even," for neither side can truly claim to be free from fault. Both sides might with advantage pay attention to their own faults, for while it is impossible to sell shoddy apparatus, the days when good wine needed no bush are unfortunately over. It is only in this way, we are certain, that the present unsatisfactory state of business may be remedied.

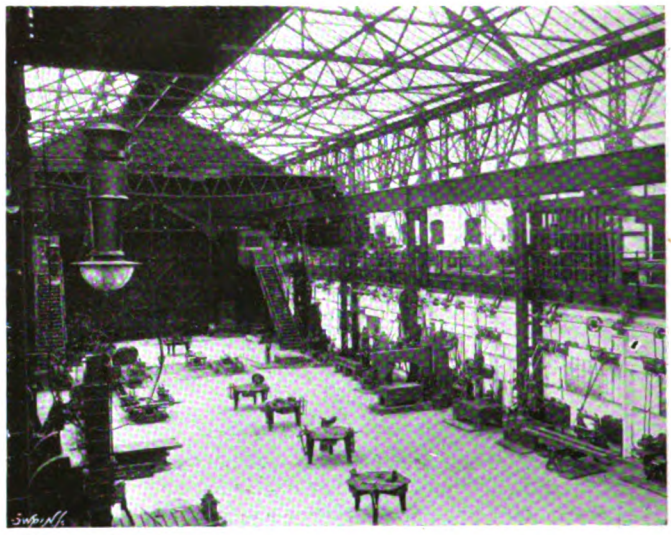
Westinghouse Magazine Flame Arc Lamps. . .

THERE has been a great demand of late for arc lamps of the flame type with long burning hours. This has been met in a variety of ways, but the British Westinghouse Co., after exhaustive experiments, gave their vote in favour of a lamp in which converging carbons are used. The excessive length of carbon necessary for the single carbon lamp makes it impossible, for various reasons, the principal of which is, perhaps, the brittleness of a long thin carbon rod, to effect long burning hours with this type; but with the Westinghouse magazine lamp now put on the market a burning of 45 to 50 hours can be guaranteed. The lamp is of the inclined carbon type, containing magazines holding 10 pairs of carbons. The use of these magazines enables, it is claimed, the employment of carbons smaller in diameter and of cheaper quality than those used in an ordinary flame lamp.



Figs. 1 and 3.—Westinghouse Flame Lamp for Workshop Lighting.

The lamp is controlled electrically by means of shunt and series solenoids, as is the case with their standard "Arcturus" flame lamp. The carbons are positively fed downwards by means of a carrier which is moved by a single endless chain. The chain is operated by a ratchet wheel and pawl, the pawl being actuated by a solenoid. As one pair of carbons is consumed the second pair is automatically pushed into position and fed downwards. The horizontal feed of the Westinghouse Bremer lamp is retained.

By means of a special ventilation and deposit-free cover all fumes and products of combustion are carried into the open air, thus keeping the globes perfectly clean and unaffected by the arc fumes throughout the run.

The mechanism of the lamp is entirely isolated from the arc fumes; but is, on the other hand, easily exposed for inspection, as only two screws need to be withdrawn when it is required to inspect any part of the lamp.

Each lamp is fitted with a substitutional resistance and cutout, so that the failure of one lamp does not interfere with the working of the rest of the series. In addition, an automatic arrangement is fixed to the lamp that cuts off the current from the ratchet coil when all the carbons are consumed. This enables a lamp to be trimmed while the rest of the series is burning.

Engineers and others responsible for effective public lighting by arc lamps have experienced trouble arising from constant renewal of contacts. The simple ratchet of the Westinghouse lamp, it is claimed, completely solves this difficulty, for it may be at work many months without showing any sign of wear. Attention, too, may be drawn to the chain. Instead of adopting a complicated lever action, necessary in the design of most makes, the Westinghouse lamp has an ordinary roller chain. The cost of general upkeep is remarkably low. In one case 10 of the Westinghouse magazine lamps that had superseded another make saved £5 in four months in upkeep alone.

All parts of the lamp are made to template and are interchangeable.

In summarising the special features of this lamp we may

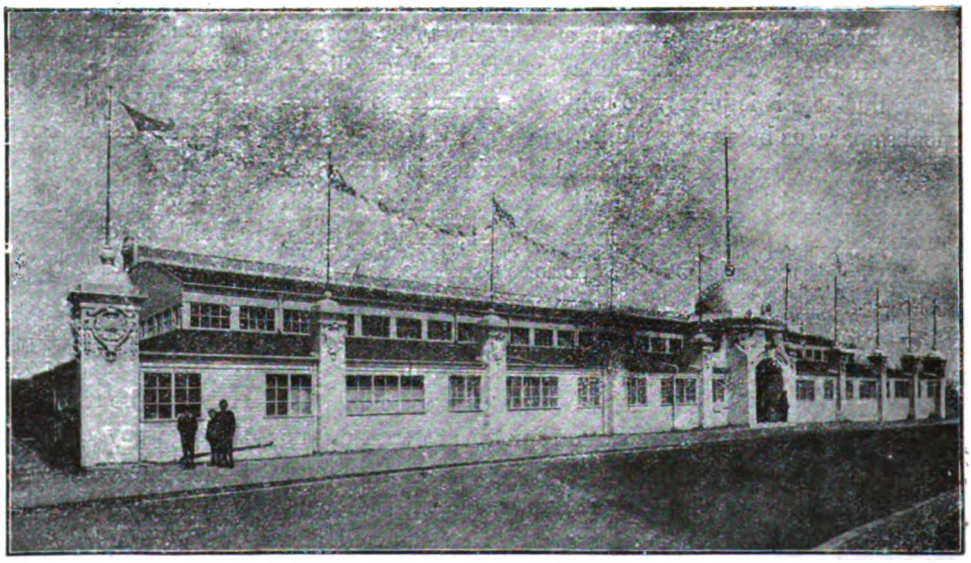


Fig. 2.—Westinghouse Flame Lamps Outside a Skating Rink.

Digitized by Google

mention the low upkeep costs, low carbon and trimming costs, low watt consumption, long burning hours (45 to 50 hours are guaranteed under this head), and that the working parts are isolated from fumes.

As showing the wide application which Westinghouse flame arc lamps are receiving at the present time, we may mention that they have recently supplied 180 to the Great Central Railway, 32 to the North British Locomotive Co., 12 to the Maypole Dairy Co., 10 to Jacksons (Ltd.), hatters; 12 to the Empire Skating Rink, Birmingham; 20 to the Birmingham Arcade; 12 to R. O'Brien & Co., for Blackpool South Shore fair ground; 8 to Whipp & Bourne, for Rawtenstall street lighting; 5 to the Lancashire & Yorkshire Railway, Horwich; 120 to the Hang Yeng Iron & Steel Works, China; 32 to the Challenge Cycle Co., Coventry; 8 to the Llandudno Pier Co.; 288 to the Humber Cycle Works; 14 (magazine type) to the Stretford U.D.C.; 10 to Robson & Coleman, of Newcastle, for skating rink lighting; 4 to the Buenos Ayres & Pacific Railway; 10 to Pease & Partners, Darlington, for colliery lighting.

Crompton Flame Arc Lamps, Some Typical Applications.

IT is practically three years ago since the Crompton-Blondel flame arc lamp was placed on the market, and in that time it has made substantial progress and is being used for the illumination of shops, streets and many other places where a good artificial light is a necessity.

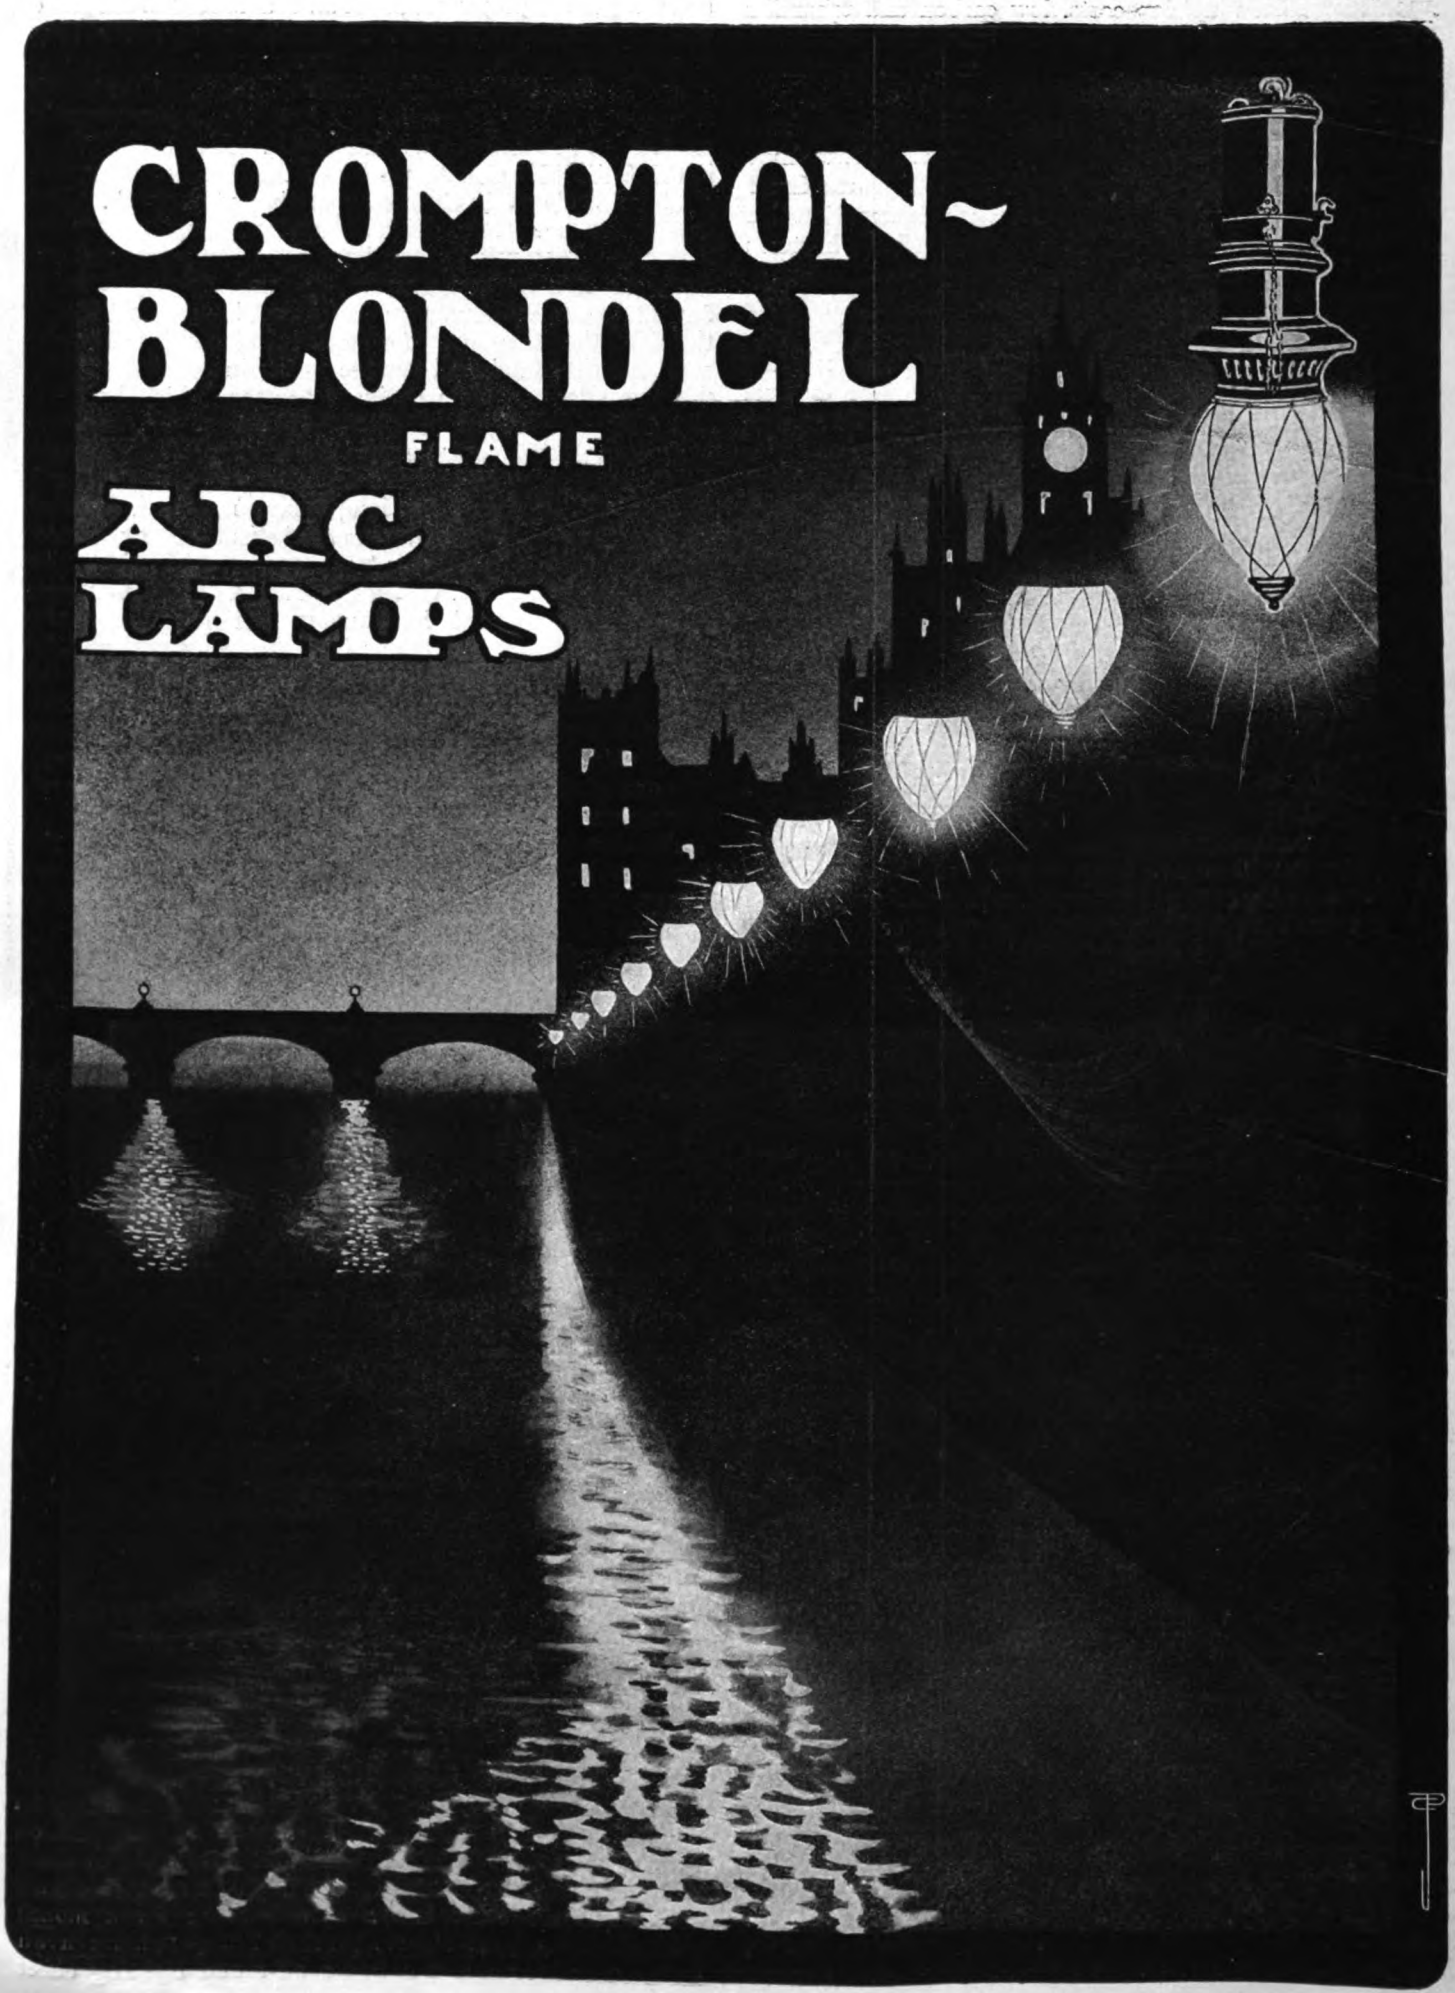
The Lighting of Shieldhall Sewage Works by Crompton Lamps.

The essential features of this lamp are, it will be remembered, heavy mineralised carbons placed in a vertical position, the positive being more heavily mineralised and larger than the negative. It is also always placed below the negative. The mechanism of the lamp is very similar to that employed in the well known Crompton open type lamp, though it has a somewhat longer stroke and a more delicate feed. By means of a specially ventilated corona and ash pan the proper supply of air is admitted to the globe and the burnt gas and fumes are carried away, so that they cannot damage the mechanism in any way.

As showing the wide application of Messrs. Crompton's lamps, mention may be made of a few installations recently carried out by Messrs. Crompton & Co. The first of these is the Shieldhall sewage works of the Glasgow Corporation, and is shown in the accompanying photograph. The installation consists of 35 "SS" pattern lamps, ordered in January. They take, when burning, 5 amperes and are arranged five in series on a 250 volt circuit, burning for 32 hours without recarboning. They were ordered through the Glasgow Corporation Electricity Department for the Shieldhall sewage works in connection with the new Glasgow main drainage scheme, which has cost the City of Glasgow over £2,000,000 sterling. These lamps are similar to some previously supplied by Messrs. Crompton to Dalmuir for the drainage tanks on the north bank of the Clyde. These lamps have now been burning for some years without cutouts or substitutional resistances and have given, we understand, every satisfaction. An installation at Messrs. Charles L. Reis & Co. of 10-ampere flame lamps, ordered in January last year, may also be mentioned. These lamps burn five in series on 250 volts for 10 hours without recarboning and are fitted with internal automatic cutouts and independent substitutional resistances. They are in a prominent position in a chief thoroughfare in Glasgow and have proved, we are glad to hear, a good advertisement for Messrs. Crompton.

Another somewhat similar instance of lighting of the quasi-outdoor kind is supplied by B 12 7-ampere flame lamps, burning five in series on 250 volts for 18 hours without recarboning and fitted with internal automatic cut-outs and hooded type substitutional resistances, which were ordered in September, 1909, through Messrs Anderson & Munro, for lighting the Arcade in Glasgow. Messrs. Crompton obtained this order in competition with a number of other makers and were able to show that their carbon cost was lowest, and as a sample circuit of each of the other lamps were burning for a month alongside them, it was shown that their 7 ampere lamp gave a better distribution and a better all-round lighting effect

Digitized by Google



Digitized by Google

than their rivals' which were consuming considerably more current.

Mention may also be made of 5-ampere B 12 lamps, ordered in August, 1908, by Messrs. John Irwin, which have been so successful that Messrs. Crompton have this month received a repeat order for these lamps. The lamps will then be run six in series on 250 volts. They are fitted with internal cutouts and independent substitutional resistances. The lighting of the street is also carried out by means of the same lamp.

An example of shop lighting at Forsyth's, Glasgow, may also be mentioned. This consists of ten B 12 10-ampere lamps which were supplied in March of last year. These lamps are burning five in series on 250 volts, using white flame carbons, and are burning without cutouts or substitutional resistances, and have given every satisfaction. There are in addition a large number of Messrs. Crompton's enclosed lamps used for the lighting in the interior of this shop, and they recently received an order for 38 further enclosed lamps for interior lighting from the same firm.

These are merely a few detailed instances of recent installations of the Crompton-Blondel flame arc lamp, but as showing the extent of its success the following instances may be cited of its wide application in the lighting of factories, streets, shipyards and other open spaces. Messrs. Marshall, Sons & Co., of Gainsboro', have just put in over 500 of these lamps for shop and yard lighting, and altogether over 1,000 Crompton flame arc lamps are now in these works. Messrs. Armstrong, Whitworth & Co. have just ordered 50, bringing the number of Crompton lamps in their works to considerably over 300. Other recent orders comprise 28 flame arcs from Messrs. W. E. O. Williams & Co., of Newport; 25 from Messrs. Humphries & Sons, of Kidderminster; 40 from Messrs. Balfour, Beatty, for the lighting of Llanelly; and a large number for Messrs. Dorman Long's works at Middlesbrough, Messrs. Ruston Proctor of Lincoln, the Avonside Engine Co., Southampton Docks, Swansea Harbour Trust, and Boston Harbour where the lighting is completely carried out by Crompton lamps. Town lighting, too, is well represented, and in the case of Lincoln and Yarmouth the Corporation recently decided, after careful experiments, to instal the Crompton-Blondel flame arc lamp, which, in each case, is replacing the old Crompton P. type lamps which have been running in these towns with considerable success for a number of years. It would seem, therefore, that the Blondel lamp is assured of a large measure of the success which signally marked the open and enclosed type Crompton lamps, which have held the market for so many years.

The "Metroflam" Lamp.

A FIRM who have long been known as pre-eminent in the arc lamp world are Messrs. Johnson & Phillips, of Old Charlton. They were among the earliest to manufacture this type of lamp and, keeping pace with modern developments, now turn out an efficient magazine flame lamp, known as the "Metroflam." This lamp burns for 70 hours at one trimming. There is, it is claimed, no period of extinction, as the carbon changes, while no cleaning of the working parts is necessary, though the globe and furnace, of course, require wiping. The efficiency is 6 c.p. per watt, the cost of the carbons is low, and they are supplied in short lengths, so there is no wastage due to breakages in trimming, while their first cost is also moderate. It may, in passing, be mentioned that the distribution of light required for a particular purpose can easily be effected by adjusting the lamp to a suitable height.

Turning to details, the non-extinction of the "Metroflam" lamp is secured by arranging that before one pair of carbons has ceased to burn, another pair comes into contact; the arc is therefore at once formed between them, simultaneously disappearing from between the ends of the

Fig. 1.—"Bell" Arc Lamp Lowering Gear.

old pair. This process is effected by dividing both the positive and negative magazines into two separate compartments (four in all), having an endless chain passing down between the two sets of carbons. Tappets on the sides of this chain push down one carbon from one side and

Digitized by Google

from the other alternately, that is to say, one carbon is fed from one side of the magazine and then another from the other side, and so on until all the carbons have been used. The chains are driven simultaneously by a simple ratchet, actuated by the falling weight of a small shunt solenoid core, the circuit of which is completed by the action of the differential regulating coils when the voltage becomes too great across the arc. The feed produced by this arrangement is almost imperceptible; the light is therefore extremely steady and constant.

The gear is, it is claimed, effectively protected from deposits and interference, and the magazine chamber is so

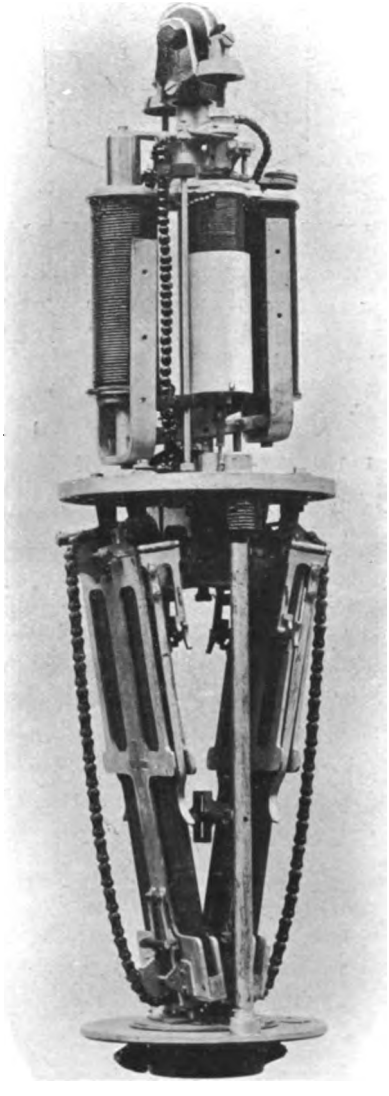

Fig. 2.—Interior of the "Metroflam" Lamp.

constructed that, as explained before, no cleaning is necessary except at long intervals. The general construction of the lamp embodies a main and shunt solenoid, which operate the two magazines sufficiently to obtain the arc. This, however, is done by means of a special toggle, which permits great delicacy of movement when the magazines are near each other, so that, however heavy the magazines may be, or should they become accidentally stiff, the feed remains still as delicate and reliable as ever.

A cut-out of solid design is also provided in the lamp, which puts in a substitutional resistance of ample proportions as required, it being impossible, it is claimed, for the arc and the resistance to remain in parallel, as the contact must be broken before the carbons begin even to separate. This is made possible by the toggle previously mentioned. Each lamp contains (in a well-ventilated chamber at the top) a substitutional resistance of ample area to prevent undue heating.

In connection with this lamp Messrs. Johnson & Phillips have been good enough to send us particulars of the Gravesend Corporation flame lamp installation. In the original scheme single-carbon open-type lamps, burning nine in series on 480 volts with a current of 12 amperes, were adopted, and these were mounted on central carriers secured chiefly to cast-iron columns, and in some cases to the steel posts used in connection with the trams. The new system embodies the use of "Metroflam" magazine lamps with swan-neck brackets and "Bell" raising and lowering gears in place of the open lamps and fittings. The flame lamps are coupled 12 in series on a 480-500 volt circuit, the current consumption being 8 amperes. Each lamp is provided with a self-contained auto cut-out and substitutional resistance, together with an isolating switch, the latter being fitted in a cast-iron box within the pillar base. The line resistances are mounted behind one of the switchboard panels at the station and are coupled to multi-contact regulating switches.

The energy consumed by the flame lamps is only 333 watts each, against 640 watts with the original open lamps. The life at each trimming is 80 hours, *i.e.*, five times as long as the older lamps, so thus a large saving is effected on these two heads alone, in addition to which the maintenance costs are practically negligible. The employment of contact gears for lowering the lamps for trimming is another factor which conduces to the economical working of the installation.

The "Metroflam" lamp and "Bell" contact device, referred to above, have both been designed by Mr. James Brockie. This contact gear is an up-to-date device taking the weight of the lamp off the lifting rope, and making electrical contact between the supply mains and the lamp terminals. In construction it is quite simple, a well-known and proved principle being employed in an entirely novel manner. It contains no springs or pawls. The lamp is suspended from a strong malleable iron hanger, and its weight is carried by substantial lugs. Electrical spigot and socket self-cleaning contacts of ample size are employed, insulated in the very best manner with steatite cones, only one size of insulator being used. The action of the gear is, it is claimed, absolutely reliable, and the lamp always returns to its original position. Reversal of polarity is thus impossible. A patent self-locking winch is also used in connection with this gear.

For the public lighting in the Leyton district a large number of Messrs. Johnson & Phillips' "Metroflam" magazine lamps and "Bell" contact gears and accessories have recently been installed. These lamps are identical with those in use at Gravesend and elsewhere, but they are coupled three in series on a 150-volt circuit. Although many of the lamps are fixed to the tramway columns the vibration due to passing cars does not, Messrs. Johnson & Phillips inform us, affect the efficient performance and steady burning of the lamps in the slightest degree.

It is interesting to note that before the placing of the order for the Leyton lamps, the engineer for the U.D.C. (Mr. F. Harman Lewis) carried out a lengthy and severe elimination test with a number of the best known lamps,

and after a careful comparison of the actual results obtained, the "Metroflam" was selected, being placed first on the list of "suitability for public lighting."

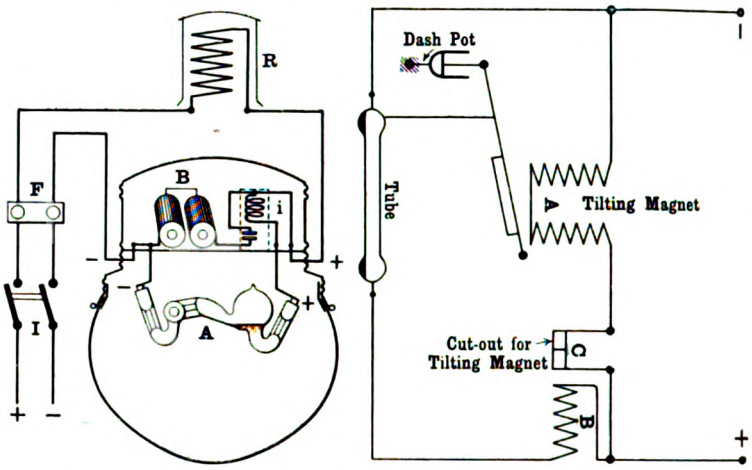
One very important feature which is much appreciated in this and other "Metroflam" installations is the absence of deposit in the interior of the lamps even after many months' operation, no cleaning of the mechanism by the trimmer being needed. A photograph of the Leyton lamps taken at night appears on p. 120.

The "Metroflam" lamp has been placed on the market to meet the requirements of corporations and contractors who require a lamp which is absolutely dependable, economical to run (both as to current and carbons), has a really long duration, burns with perfect steadiness—yielding a light that does not emulate the chameleon—and costs little or nothing to maintain. For these reasons it is specially suitable for street, railway station and goods yard lighting, harbour and dock illumination and similar services. The convenience of the lamp is greatly enhanced by the use of the "Bell" contact gear, which, together with the exceptionally long duration obtained, reduces the cost of attendance very appreciably, so that only a single trimmer is required to attend to all except the very largest installations.

OSRAM-LAMPS

Westinghouse Silica Lamp.

ELECTRIC lighting always seems to be in a state of development. Sometimes its progress is slow, and over a period of, say, 12 months we can only point to improvements in the working details of the apparatus used, which, though leading to increased efficiency, mark no great turning point in its history. At other times progress seems to take place by leaps and bounds. One of



Figs. 1 and 2.—Diagrams of the Westinghouse Silica Lamp.

these occasions was doubtless when the flame arc lamp was introduced, and, it is claimed, that now the vapour lamp is receiving a wide application we have reached another.

The Westinghouse Cooper-Hewitt Co., who manufacture the Westinghouse silica lamp in this country, claim that it provides an ideal light for railway depots, docks and wharves, streets and public places, factory yards, as well as for the interior lighting of markets, sheds, machine shops, foundries and steel works. This lamp has the

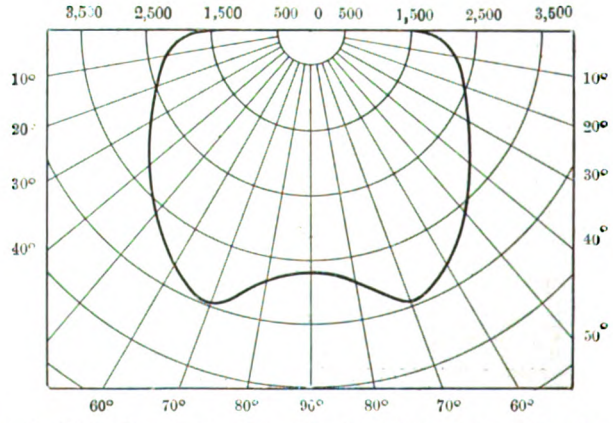


Fig. 3.—Light Distribution Curve for the Westinghouse Silica Lamp.

further advantages that it requires neither re-carboning or cleaning, so that its maintenance is very low, while, unlike many vapour lamps, the light given out is of an agreeable bluish-white colour which allows globes of clear and very slightly opal glass to be used. In this way a maximum of the light produced is available for useful purposes.

The Westinghouse silica lamp may be divided into two parts—(1) the base, on which, and totally enclosed, is the mechanism; (2) the vapour tube, mounted underneath the base and enclosed by an opal or clear globe. In the 3,000

Digitized by Google

c.p. lamp the luminous portion of this tube is about 4 in. long. The tube is held in a tilting cradle, and is operated by a link projecting through the base. The upper end of this operating link is connected to the magnet of a large solenoid mounted on the upper side of the base and is coupled to a dashpot arrangement. A general diagram of the arrangement is shown in Fig. 1, while photographs are reproduced showing the actual appearance.

The tilting operation necessary to produce the mercury arc is automatic, and is performed by the large solenoid fixed in the centre of the base, working in conjunction with an automatic cut-out arrangement, in which is embodied the smaller coil B. In the diagram the tilting solenoid is represented by A and the cut-out coil by B. On switching on, the current flows through the cut-out contacts C, and through the coils of B, to the negative main. The energising of the coils at A causes the magnet to lift, thus tilting the cradle and lamp-tube. The tilting of the quartz tube causes the mercury contained at the right-hand end to flow down towards the other end, completing the tube circuit. The coil B is in series with the tube, and now comes into operation, breaking the solenoid circuit at C. This de-energises the solenoid A. The magnet then falls away into a slanting position, the balance-weights fixed to the cradle being large enough to ensure this. The tube remains in this position while burning and when switched off, and is tilted automatically once only at starting. The source of light consists of vaporised mercury, a continual cycle of vaporisation and condensation proceeding while the lamp is burning. The resulting light is of a bluish-white character, the temperature of the quartz tube being such that it glows and provides rays, which, to some extent, correct the pronounced colour of the ordinary mercury-vapour light.

As it is essential that the correct polarity should be observed, in order to prevent damage to the tube, a simple automatic device is introduced into the mechanism to ensure this. This consists of a small permanent magnet suspended from the arm which carries the dashpot cylinder. If the polarity is correct, the lower end of this permanent magnet is repelled from the locking-piece on the magnet arm below, and the lamp is tilted. If, on the other hand, the polarity is incorrect, the permanent magnet is attracted to and fouls the locking-piece, and the lamp-cradle cannot be drawn up. The lamps are fitted with clear or opal globes, and in outward appearance do not differ greatly from arc lamps. All the mechanism is entirely enclosed and protected from dust. The globes are provided with chains, and for inspection purposes can be lowered away from the base to the length of these chains.

The quartz tubes, which form the most expensive part of the lamp, are guaranteed by the makers for 1,000 hours. The average life is, however, much higher, and 3,000 hours is commonly experienced. Tubes that have given out through loss of vacuum can be repaired. The lamps have the low consumption of 0·25 watt per candle-power. They are intended for direct-current circuits for working in parallel. The light is steady, and as all the parts are above the source of light, which is of comparatively large area, no shadows are thrown on the globe and the diffusion is good.

The light-distribution curve for a lamp taking 3·5 amperes at 250 volts is given in Fig. 3, and shows a mean hemispherical candle-power of over 3,000, with a maximum illumination of 4,500 c.p. at 65 deg. to 70 deg. to the horizontal. The running costs of a 1,200 c.p. Westinghouse silica lamp, taking 4 amperes at 100 volts, work out, it is claimed at 1·1d. per hour, when energy costs 3d. per unit. This sum includes an allowance for replacement of tubes. This is calculated on a 2,000-hour life for the tubes. If the life is cut down in the calculation to the 1,000 hours for which the tubes are guaranteed, the cost per hour is 1·54d. These figures compare with 2·565d. for the flame arc, and 2·88d. for the enclosed arc, using ordinary carbons of similar candle-power on line voltages of 65 and 110 respectively. In the case of the Westinghouse silica lamp the figure of 1·20d. is given as the cost for current, and 0·17d. as the allowance for the replacement of the tube on the 2,000-hour basis. The comparative figures for the flame arc are given as 0·975d. for current, with 0·29d. for cost of carbons, in addition to which 1·2d. is included as the cost of maintenance, cleaning, labour, &c. In the case of the enclosed arc the cost of current is placed at 2·64d., of the carbons at 0·04d., and of maintenance, cleaning, &c., per hour at 0·2d.

Owing to the high efficiency, combined with the long life of the burners, together with the fact that the lamps require no attention during running, the total running cost per hour works out considerably less than that of ordinary or flame arc lighting. Further, no hoisting winches or contact suspension gear need be provided. This type of lamp is, it is claimed, unique in so far that a single lamp can be provided for use on a 200-250 volt circuit.

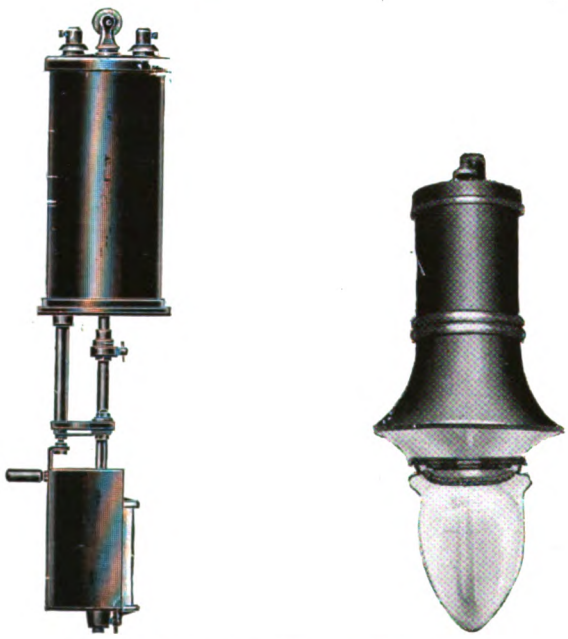
Foster Arc Lamps.

THE Foster Arc Lamp & Engineering Co. have been good enough to supply us with details of a number of places where their lamps are in use. The lamps made by them include a "hot-wire" lamp, operating on the well-known principle of the expansion and contraction of a hot wire, and a flame lamp of the most modern kind. They are also in process of amalgamation with the Brockie-Pell Arc Lamp Co. with the result that this firm's lamps will also come under their control.

Turning to the installations themselves, we may first mention that of Mr. R. W. Oates, a draper, in Regent-street, round the lighting of which district much controversy has raged. Mr. Oates is doubtless one of those shopkeepers who protested against the adoption of gas for the street lighting and he has evidently had experience with electric light, for our contemporary, the "Drapers' Record," stated that these premises were the best lighted in Regent-street last Christmas. He is using the standard enclosed lamp of the Brockie-Pell Arc Lamp Co.,



Figs. 1 and 2.—Two Types of Foster Lamp.

the lamps being adjusted to burn two in series on a 240-volt continuous-current circuit, the consumption being 6 amperes and the hours of burning 75.

Mr. Wickham, a draper, of Tunbridge Wells, is also in favour of this type of lamp. He is employing two standard enclosed B.P. lamps in series on a 200-volt alternating-current circuit. In his new extension he is burning the above lamps in series parallel off a two-way compensator.

The lighting at Messrs. Guest, Keene & Nettlefold, Dowlais Works, Cardiff, also deserves mention. It is effected by means of the B.P. open-type lanterns, double-carbon style, 38-hour type, fitted with substitutional resistance and cut-out, the current per lamp being 10 amperes, with a voltage of 43 across the arc. Messrs. Foster have also received repeat orders for their standard enclosed lamp for use on the Royal yacht "Alexandra."

Messrs. J. Lyons & Co. (Ltd.), the caterers, are extensive users of the Foster lamp at their headquarters, Cadby Hall, and a large number of their branches, the "A" style enclosed lamp and the F.C. flame lamps are fitted, the former in single parallel on a 110-volt alternating-current circuit, the frequency being 50 and the current per lamp being 8 amperes, the hours of burning about 50. The F.C. flame lamp is running on a 110-volt circuit, two in series parallel on a two-way transformer. Each lamp takes 10 amperes, with 45 volts across the arc.

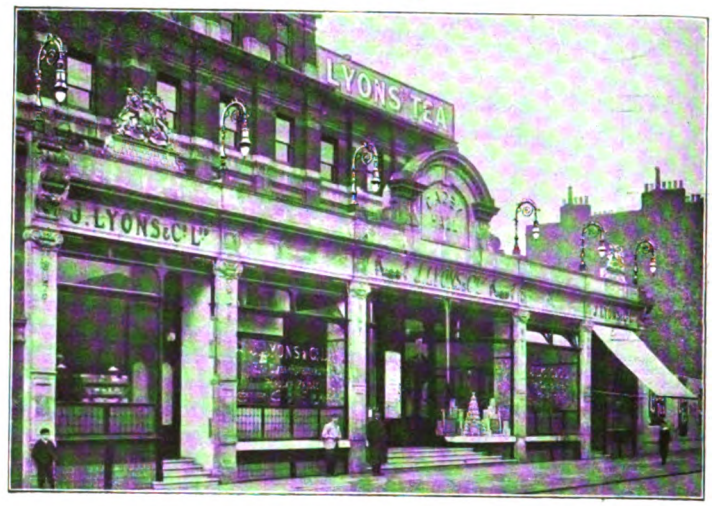


Fig. 3.—Foster Lamps at Cadby Hall.

American Photo Co. (Ltd.) use in their studios the S.P.A. lamp, and also an inverted photo lamp. The latter lamp is similiar to that shown in Fig. 1, and is simply the usual photo process lamp with a few slight alterations to allow of it being burnt upside down, *i.e.*, the carbons burning uppermost. Both these types are used for exposures.

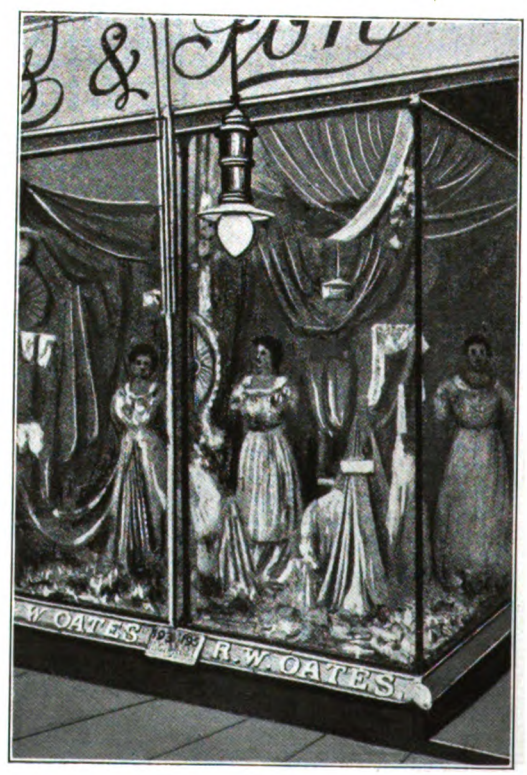

Fig. 4.—Foster Lamps for Shop Lighting in Regent Street.

The Borough of Wimbledon public street lighting is carried out by means of Messrs. Foster's well-known G.A. flame lamps. Anyone who visits Wimbledon or Raynes Park district after dark must be struck with the very brilliant lighting of that part of the world.

Digitized by Google

EXCELLO
FLAME ARC WITH UNIQUE
TWO YEARS' WARRANTY

The Post Office, War Office and Admiralty are, we are informed, all warm supporters of the Foster "A" style hot-wire lamp. This is shown in one of the accompanying illustrations. Foster's "A" style lamp burns at 6 amperes on either alternating or direct current, singly on 100 volts, or two in series on 200-220 volts, the hours of burning being from 50 to 60.

Jandus Regenerative Flame Arcs.

AMONG the recent places where the Jandus Arc Lamp & Electric Co. have introduced their well-known regenerative flame arc lamps we may mention the town of Grimsby, where 80 lamps of this kind, adjusted to burn four in series on a 230-volt direct-current circuit, have just been erected. In connection with this installation a special panel arrangement for fixing on the arc lamp column and containing line resistances, substitutional resistances, cutouts, line switches and fuses has also been supplied. These lamps have a current consumption of 8 amperes and a life per trim of 65 hours, the carbon cost per hour being only 0·116d. Fig. 2 shows some of these lamps in position at Grimsby.

The same company have also completed the lighting at the Middle Docks in the same town, 10 of the regenerative lamps being arranged for burning five in series on 500 to 550 direct-current circuit. These lamps have a consumption of 6·5 amperes and are fitted with cutouts and substitutional resistances. They have a life per trim of 75 hours with a carbon cost per hour of 0·116d.

A unique lighting scheme at Margate, which has been carried out in connection with the new Glass Concert Pavilion at Westgate, may also be mentioned. In this case five regenerative lamps have been installed to burn five in series on 240-volt direct-current circuit, with a consumption of 5 amperes. The lamps, of course, are fitted with cutouts and substitutional resistances, and have a life per trim of 80 hours, the carbon cost per hour being 0·095d. At Halifax the Jandus Co. have installed 30 lamps with a current consumption of 8 amperes. These are arranged to burn five and four in series on a 230-volt direct-current circuit and have a life per trim of 65 hours, the carbon cost per hour being 0·116d. For the lighting of the Mercantile Dry Docks, Jarrow, they have just supplied 30 regenerative lamps adjusted to burn singly off internal choker on a 110-volt alternating-current supply, the frequency being 40. These lamps consume 7·3 amperes and have a life per trim of 65 hours and a carbon cost of 0·116d.

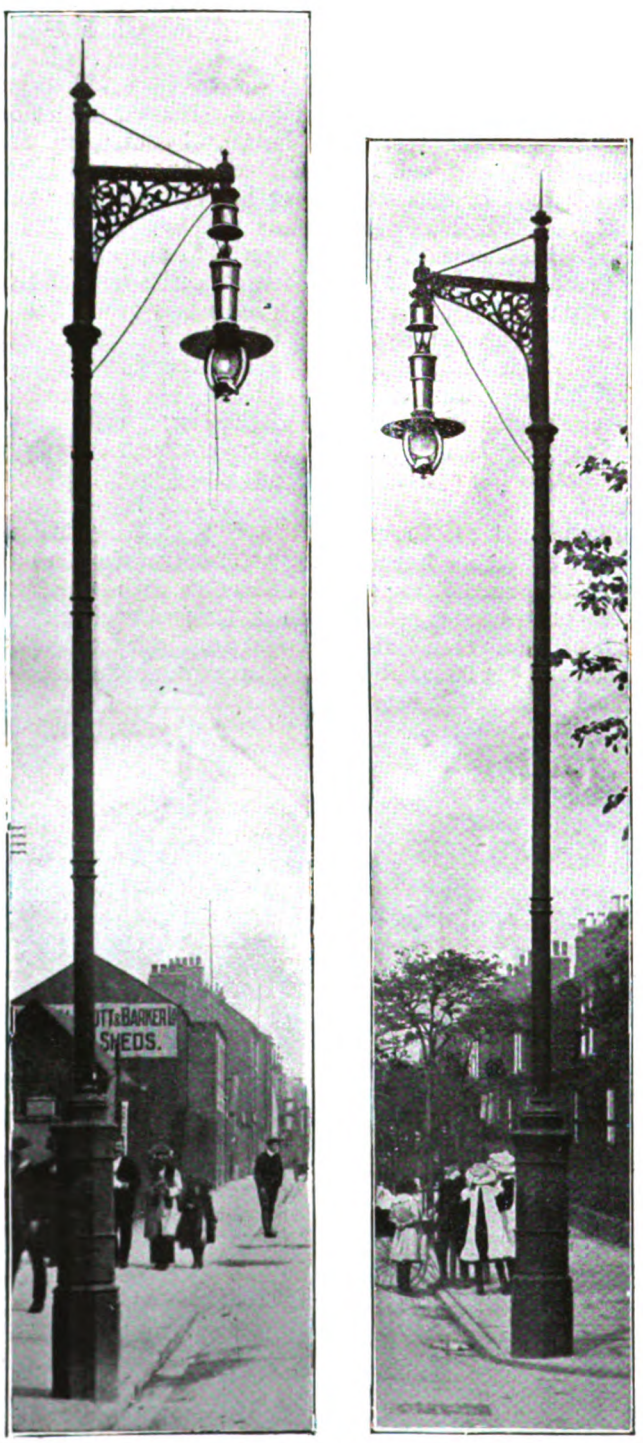
Further, at the foundry of Sir B. Samuelson, Middlesbrough, 21 lamps burning singly off a transformer on an alternating-current supply of 440 volts, with a frequency of 40, have been supplied. These lamps have an adjustment of 8 amperes and a life per trim of 65 hours with a carbon cost per hour of 0·116d. Quite a number of lamps for street lighting have been supplied to Bradford Corporation.

Fig. 1.—Photo. of Jandus Lamps, showing the Excellent Horizontal Distribution.

Digitized by Google

These are adjusted to burn two in series on a 230-volt direct-current circuit with an adjustment of 5 amperes. They have a life per trim of 75 hours and a carbon cost per hour of 0·1d.

Fig. 1 shows the excellent horizontal distribution obtained with a Jandus 8-ampere lamp. This photograph was taken between 12:30 and 1 o'clock in the morning and no other lamps but the two arc lamps shown in the photo-



Jandus Lamp for Street Lighting at Grimsby.

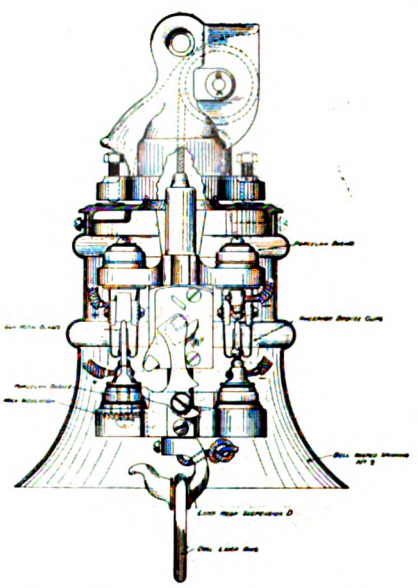
graph were alight. Mention may also be made of the bandstand lighting in Lister Park, Bradford. This has just been executed by the Corporation Electricity department, and the cost of the installation has been defrayed by the Lister Park committee. The lighting is effected by four new Jandus regenerative flame arc lamps of 3,000 c.p. each—12,000 in all. They work in series on 230 volts and consume 5 amperes.

Arc Lamp Lowering Gear.

THE North Western Electrical Appliance Co., of Cathcart, Glasgow, who have made a speciality of lowering gear, have introduced during the year several improved types of gears, to meet different requirements, necessitated by the advent of flame lamps and the general advancement in arc lighting.

The increased necessity of greater efficiency and reduced maintenance economies has necessitated to a large extent the adoption of raising and lowering gear. During the past year the demand has, we understand, exceeded all previous records.

This firm have new types for two, three and four connections and also for two and three contacts with switch clip spring contacts for short-circuiting lamps or connecting the lamp through its substitutional resistance while down



Section of North Western Co.'s Arc Lamp Contact Gear.

for cleaning or repairs. Such an arrangement has considerable advantages beyond keeping the series lamps burning, in that faults can readily be detected by simply lowering the lamp slightly till the faulty lamp is located.

The North Western Co. have also introduced new types for high-tension work and central carrier lowering heads, both of the swing out type and the span rod type. They have gears for span wire and all classes of private and public installations, and are suitable for practically any make of lamp or fixings.

Their self-sustaining positive-acting safety winch is an ideal type for arc lighting, as the lamp can be readily got up and down quickly without damaging the globes in high winds. The direct action also gives a sensitive feel and thus prevents over-straining of the rope which is liable with geared winches where only a fraction of the weight is felt. The winch, although direct-acting, has an automatic smooth continuous secure clutch which will maintain without jar any weight required for arc lamps. They are tested up to 200 lb. The weight of the lamp is not on the hanger when lowered but is so in raising, which gives a sensitive feel.

This firm has adopted throughout hard-drawn phosphor bronze clip-knife contacts. They maintain that by this design there is less liability of the lamp breaking contact in high winds, and a strong sliding spring cleaning contact is always assured. There is no movement at the pillar end of their gears and only a slight oscillation at the foot, which is operated by inclines and is direct, positive in its action and cannot get out of order.

Digitized by Google

Long Burning Flame Arc Lamp.

THE long burning flame arc lamp just placed on the market by the Electrical Co. gives 80 to 100 burning hours with one pair of carbons. That means that if the lamp be used in a street during the winter months only one trim per week instead of per day would be required. Besides this the cost of the expensive flame carbons is reduced to an insignificant amount, because the new lamp is a carbon saver? It only consumes one pair, not a dozen or more pairs like a magazine lamp.

The small current consumption of modern flame arc lamps, and the tendency of the price of current to fall has had the unfortunate effect of making those electricity supply companies who have to deal with street lighting, actual buyers and sellers of carbons and labour, for use with their arc lamps. The new lamp reduces the cost of these maintenance charges to about one-third, and enables the most economical relations between cost of current and upkeep to be obtained.

Fig. 1.—External View of Electrical Co.'s Flame Lamp.

The principle adopted in this lamp to secure long-burning periods is the total enclosure of the arc. The difficulty, however, that has to be overcome, is satisfactorily to dispose of the fumes resulting from the arc, which, owing to enclosure of the latter, cannot be disposed of by ordinary methods of ventilation. This is effected by an entirely novel arrangement of the globe and burning chamber. The globe is divided into two parts. The upper portion is clear, to allow of the light being distributed. The lower portion is opaque, as clear glass would serve no useful purpose. The appearance is also better. Naturally this lower portion is cooler than the upper, which is heated by the arc. Consequently all the heavy ash sinks to the bottom.

Above the arc itself a deposit chamber is arranged which, owing to its large radiation surface, causes all the lighter gases to condense inside it. A constant circulation is thus set up, and the ash or deposit is so completely got rid of, that the loss of light through the clear portion after 100 hours of burning is insignificant.

The mechanism in the direct-current lamp is of the differential pattern, while in the alternating current it is of the motor type. The latter is strengthened to give a rapid ignition. Both types are, it is claimed, the most perfect that can be produced.

The arc voltage is about 45, so that two lamps can be burnt on 110 volts, four on 220 volts, and five on 250 volts. It is recommended that a series of over two lamps should be fitted with automatic safety devices.

The curve in Fig. 2 shows how the light is distributed. The maximum is at an angle of 20 deg. under the horizontal, so that the lamps need not be hung so high as an ordinary flame arc with converging carbons. Thus the cost of poles and installation is reduced. The power-factor of the alternating-current lamp is 0·86, and the mean hemispherical candle-power in Hefner candles is 800 for the 8-ampere lamp, and 1,500 for the 12-ampere lamp. The practical specific energy consumption being of the order of 0·33 to 0·36 watts per candle-power.

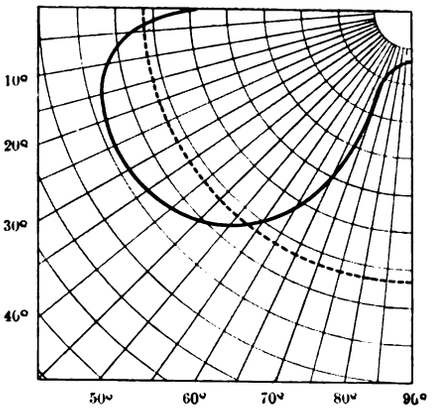


Fig. 2.—Distribution Curve from Electrical Co.'s Flame Lamp.

The lamp is intended for the illumination of open spaces of all sorts. First and foremost comes street lighting, where it will be specially useful to compete successfully against gas. Then, naturally, it will be used for railway yards, sidings, &c., factories, machine shops, shipbuilding yards and such places.

The "Butt" Arc Lamp.

A GLANCE through the articles which appear on other pages of this issue will clearly show that the mechanism of the flame arc lamp is going through a period of transition. Many "fakements" have been introduced with a view to simplifying the working of the lamp, and, though these are often of a different nature, they all tend towards the same end.

One of the most interesting of these developments is elimination of clockwork mechanism. This is exemplified in the "Butt" lamp recently placed on the market by the General Electric Co. This lamp is, it is claimed, entirely devoid of complicated mechanism, and is self-regulated, though without regulating coils. It has one vertical carbon, while the other is slightly inclined to the vertical, the pair converging to the points where the arc is struck.

Fig. 1 shows a diagram of the mechanism at the base of the lamp. The inclined carbon is swung from striking and regulating by means of a sliding collar, *a*, on the base plate *b*. This collar is pivoted at *c*, and is swung by the rod *e*, which is attached to the plunger of the series solenoid. The holders of the two carbons are mechanically linked together, and feed down as the carbons are consumed. The tip of the perpendicular carbon rests on a swinging support, *f*, which is pivoted at *h*. Between the upper arm of the support and

Digitized by Google

the carbon is a pin, and this allows the carbon to feed slightly, so that the tip again rests on the support. By supporting the carbon chiefly from the side in this manner the breakage of the point is avoided. The support is very massive, and thus the heat is conducted away quickly from the end, while the arc being some way from it, it does not require frequent renewal. The fireclay economiser is supported from the base plate by a metal ring. On the left of this plate is an electromagnet, which provides the necessary weak field to steady and expand the arc.

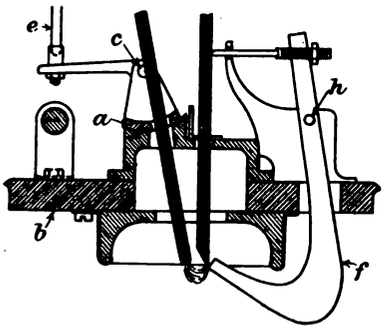

Fig. 1.—Diagram of Mechanism in Base Plate of "Butt" Lamp.

The "Butt" lamp is recommended for burning singly on 65 volts, two in series on 110 volts or four in series on 220 volts. Ordinary round-cored carbons are used, thus overcoming the great disadvantage of employing special ribbed carbons. The maintenance costs are said to be small, while there is one pattern of lamp made which is so designed and constructed as to give equally good results irrespective of the nature of the supply and current intensity. The lamp is but little affected by voltage variations, and instruments for equalising any fluctuations are quite unnecessary.

Gilbert Arc Lamps.

A VERY complete catalogue dealing with all the different variations of arc lamps made by the Gilbert Arc Lamp Co., of Chingford, has just reached us. These lamps are now in use for street lighting in over 100 towns in Great Britain, while they are also extensively employed for the illumination of goods yards, shops, skating rinks and docks.

As regards the flame arc lamps made by the company, we may first mention the "Flamme" type, which is of the four-carbon converging pattern, and can be used on either continuous or alternating-current circuits. This lamp is designed after the pattern of the "Gerrard" lamp of 20 years ago, and the mechanism is exceedingly simple. Two negative and two positive carbons are used, all converging towards one another. The carbons are simply pushed up four tubes into their holders, without removing the cover. The two negatives and two positives are then treated as one carbon, and the positives are separated from the negatives by suitable mechanism to strike and control the arc. As the carbons burn away they fall together, the converging points remaining in the same position, so that no feed mechanism is required, and when the carbons are burnt out the arc extinguishes itself.

Another type of flame lamp made by the Gilbert Company, and specially designed for use where very uniform burning is essential, is the "Beacon." It is quite free from clockwork. The feeding mechanism is, it is claimed, very sensitive, and the lamp is put into action by means of a starting resistance and switch.

Besides these lamps, mention may also be made of the standard rod feed enclosed lamps manufactured by the Gilbert Company. The various details of these are, of course, well known to our readers. Other lamps turned out by them are the photo-printing lamp, the "Trudaylyte" lamp for colour matching, and miniature lamps of various kinds.

The Development of "Excello" Lamps.

DIRECTLY the flame arc lamp was introduced its great suitability for the illumination of streets, railway stations, goods yards and other large areas was recognised, and though satisfactory from the very first it is not surprising to find that improvements have constantly been made in the details of construction, in accordance with the dictates of practical experience.

The development of this progress is of interest and we may point the remarks we have to make on the subject by giving some details, kindly supplied us by the Union Electric Co., of the improvements effected in their well-known "Excello" flame arc lamps. Among the first and greatest disadvantages of the flame arc lamp was the way in which the fumes from the carbons deposited on the globes of the lamps, with the result that extra trimming costs became necessary, while it was found that the loss of light during a 17-hour run was not less than 30 per cent. Further, the deposit adhered to the globe and effected an etching action so that the loss in light gradually increased, often reaching so high a figure as 40 per cent.

In the "Excello" lamps these difficulties were overcome by re-arranging the globes and by providing a new ash-

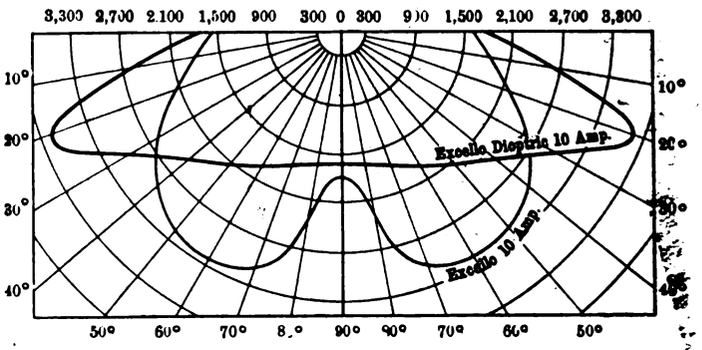

Fig. 1.—Horizontal Distribution from an "Excello" Lamp with and without Dioptric Globe.

tray. In the old lamp the air entered through the ash tray, and not only gradually circulated along the sides of the globe, but also rose direct to the arc. It here became charged with the fumes and deposit given off from the arc, and, as the arc was partially enclosed by the economiser, was deflected sideways towards the cooler parts where it met with air cooled by contact with the globe surface. Under these conditions the circulation was not continuously upwards, and the cooled air tended to pass over the inner surface of the globe, leaving in its path some of the fumes and deposit with which it was charged. These rapidly attacked and coated the inner surface of the globe rendering it more or less opaque.

In the new design of deposit-free cover an inner and outer globe are provided; these are connected together at the top by a diaphragm, thus forming an enclosed air space between the two globes. The air enters through the ash tray, is slightly heated in the space between the two globes, and rising through the inner globe to the arc, is charged with the fumes and deposit from same, and then deflected sideways towards the inner surface of the inner globe. If these surfaces were as cool as the outer globe the same course of circulation would be followed as previously mentioned, and deposit would be formed on the inner globe,

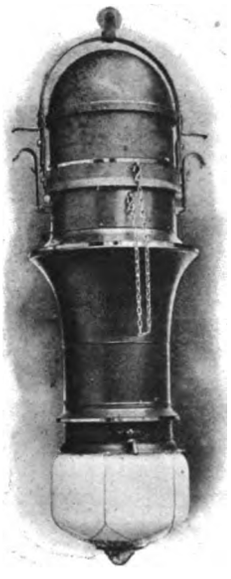
"SUNSHINE"

FLAME ARC LAMPS.

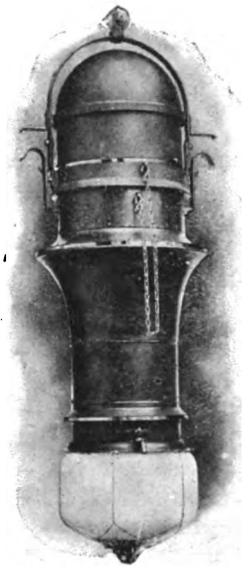


They are Flame Lamps with a character.

The character is supported by many years' reputation.

It is the result of years of experience and of scrupulous attention to essential details.

If you have not adopted them, follow the leading Electrical Houses and do so at once.



Do not forget:

(1) There is no other lamp so perfect in every detail.

(2) The "Sunshine" Mechanism is differentially controlled by both pressure and current. No flickering like non-mechanism lamps.

(3) The "Sunshine" finish is as handsome as the design and workmanship. It is the lamp for the man of good taste. It costs nothing extra to have a handsome lamp.

(4) Trimmers like "Sunshines" because they are easy to clean, easy to trim, and are thoroughly reliable.

THE ELECTRICAL CO., Ltd.,

MACHINE AND APPARATUS DEPT.,

but, owing to the proximity of the inner globe to the arc the temperature is much higher, and this temperature is easily maintained due to the stagnant air between the inner and the outer globe forming the best heat insulator. The effect, therefore, is that the course of the air through the lamp is practically continuously upwards, and both globes remain free from deposit or etching action. The patent ash tray is designed to act as a wind trap, deflecting any air which impinges on it upwards into the globe and distributing under a disc inside the globe. The relative

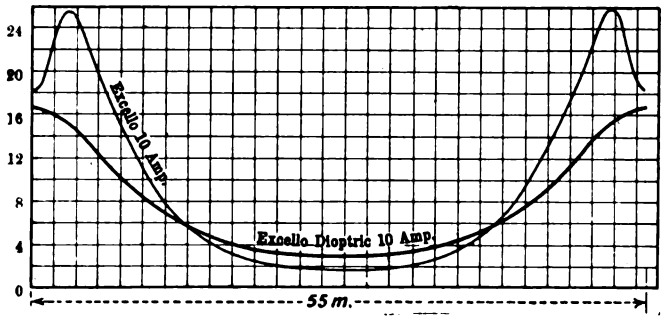

Fig. 2.—Surface Distribution from "Excello" Lamps with and without Dioptric Globes.

proportion of the deflecting surfaces in the ash tray are so arranged that the air pressure in the desired direction inside the lamp is greater than the opposing pressure produced by the same air current acting through the aperture at the top of the globe carrier. This ensures, it is claimed, a constant air circulation in the desired direction even in violent storms, and practice has shown that this arrangement of the globes and ash tray ensures clear glass globes under any conditions of wind and weather.

The arrangement of globes mentioned above enabled a further step in the improvement of the lamp to be taken.

Fig. 3.—"Excello" Lamps for Shop Lighting.

It is well known that the distribution of light from inclined carbons is not very satisfactory for the illumination of large areas, as the maximum light is emitted at 60 deg. below the horizontal plane, giving rise to an unequal surface illumination. This disadvantage has been overcome by the provision of dioptric prisms arranged on the outer side of the inner globe. The alteration in distribution obtained with a 10 ampere "Excello" lamp with the new arrangement is shown in Figs. 1 and 2.

The Union Electric Co. guarantee all Excello, Kohinoor and other arc lamps sold by them to be free from all infringement of patents, and undertake to defend all claims or actions for infringement of British patents in respect of their sale or use. They also guarantee that expert skill has been used in the selection of the materials and in the construction and testing of their arc lamps; and will, subject to conditions as to proper maintenance, make good, free of cost to the user, any defects which may occur during a period of two years from the original date of despatch of any arc lamp, and which are due to any faulty materials or workmanship. This guarantee includes the replacement or repair of the defective parts, but does not admit liability for any indirect, consequential or contingent losses or damages.

Drake & Gorham's Arc Lamps.

THE profession and trade of electrical engineering is now getting on in years, and one may, therefore, now look back to 15 years ago and yet find a time when the ideas of to-day were still in existence, present day development being foreshadowed in the work of that time. In the present issue of the INDUSTRIAL SUPPLEMENT we are dealing more particularly with arc lamps. The development of this type of illuminant during the past 15 years has been great, and this satisfactory state of things has, we think our readers will agree, been due in no little part to the efforts of Messrs. Drake & Gorham. This firm has, in fact, been closely associated with arc lamps over the period mentioned, and from their present range of lamps it is evident that they intend to remain in the front rank of this section of the business. They claim to have attained the ideal—low price and running costs combined with simple yet substantial construction—in both their flame and enclosed types of lamps. These lamps are free from clockwork, and, what is even more important, shunt coils—the weak part of most arc lamps. Large numbers of lamps are in use throughout the United Kingdom working under a variety of conditions in a satisfactory manner, as the various repeat orders testify.

Messrs. Drake & Gorham's latest venture is the "Butt" lamp, which is being made under the "Conta" patent. The external and interior views of this lamp are shown in the accompanying illustrations. This lamp, it will be remembered, is devoid of complicated mechanism and clockwork parts, and is self-regulated though without regulation coils. It has one vertical and one converging carbon. The "Butt" lamp is recommended for burning singly on 65 volts, two in series on 110 volts or four in series on 220 volts. Ordinary round-cored carbons are used, thus overcoming the great disadvantage of employing special ribbed carbons. The maintenance costs are said to be small, while there is one

pattern of lamp made which is so designed and constructed as to give equally good results irrespective of the nature of the supply and current intensity. The lamp is but little affected by voltage variations, and instruments for equalising any fluctuations are quite unnecessary.

Butt Flame Lamp (Conta Patents).

An important feature of the "Butt" lamp is its simplicity and solidity of construction. The rods are strongly dimensioned, brass nickel-plated and highly polished in order to limit the friction of carbon guides for the feed. The clutched carbon is in a vertical position in the centre of lamp, whilst the striking (inclined) carbon is under the influence of a magnet by which it can be moved laterally in order to strike and to form the arc. As the carbons are always in the same position, and do not move horizontally after the arc is struck, the arc chamber is very effectively sealed against the rod chamber, and the guide rods are, therefore, kept free from deposit. The clutched carbon which controls the feed touches the incombustible lower arm of the clutch lever in the economiser. This lever is pivoted, and presses with its small upper arm above the lamp plate against the carbon. As long as the slightest weight bears on the incombustible arm the lever grips the carbon sideways, thus relieving the fine carbon point. By progressive consumption the carbon becomes shorter, the pressure of the point on the lower lever arm decreases, and through that also the side pressure of the upper lever arm against the carbon becomes less and less, until finally the weight of the carbon overcomes the break action, so that it can slide.

The fact that the point of carbon is relieved eliminates, it is claimed, the danger of it being broken. It forms into a longer and longer point, thus raising the arc away from the lower lever arm, so that the latter cannot be burnt. The current is interrupted by the automatic discharge of the clutched carbon when consumed down to a small stump. All lamps are fitted with conical-shaped inside globe, the use of which prevents, it is claimed, the outside globe from becoming dirty, and thus effects a considerable saving in time and labour by dispensing with the necessity of cleaning.

This lamp is made in two types, the "long-hour" and "short-hour," both of which are suitable for burning on either continuous or alternating current.

Development of Flame Arc Lighting. . . .

THE accompanying illustration of a railway yard lighted with Siemens "Caxton" flame arc lamps is particularly interesting inasmuch as it deals with a class of arc lighting which is quite distinct from either shop window or what we might term "lighting for advertisement purposes."

The sale of flame lamps has unquestionably suffered in the past on account of electrical firms not studying sufficiently the exact conditions under which lamps are required to burn and the nature of the ground to be illuminated.

Siemens "Caxton" Flame Lamps.

Maximum and mean hemispherical candle-powers, however carefully calculated, count for little beside the effectiveness of the illumination, and a lamp which is most suitable for shop lighting is not necessarily the best lamp to put forward for the lighting of large areas of ground such as railway and shipping yards, streets, large factories, &c.

The introduction of "inclined" carbon flame lamps, which give their maximum candle-power at an angle of about 70 deg. from the horizontal, has met the requirements of those wishing to light shop fronts, &c., where it is desired to illuminate, as brilliantly as possible, the window directly beneath the lamp, and it is considered an advantage rather than otherwise if the next door neighbour's window is left in comparative darkness. That this class of lamp can also be most suitable for the lighting of large areas of ground, where the even distribution of light is desired rather than brilliant points of light, seems unreasonable, and in many instances electricity has been replaced by gas because the gas companies have been more alive to this vital distinction between two entirely different classes of lighting.

The "Caxton" lamp, which Messrs. Siemens have recently placed on the market, is essentially a lamp suitable for the lighting of large areas of ground, on account of the excellent distribution of the light. The lamp is of the vertical carbon type and burns carbons of special construction and chemical composition which are manufactured under the Blondel patents. These carbons have a very large core containing chemical salts, and, as is the case with most flame lamps, the greatest volume of light is derived from the arc itself and not from the crater of the carbons. As this is the case, it has been found an advantage with continuous-current lamps to place the positive carbon below the negative, which tends to cause the arc to burn more steadily on account of fewer particles of carbon passing through the arc from the positive to the negative electrode during combustion. The arc itself burns in a fire-clay economiser, which intensifies the light and projects it downwards in such a manner as to illuminate larger areas than has previously been possible with flame lamps of the same current. The maximum candle-power is obtained at an angle of about 30 deg. from the horizontal, and throughout the whole radius of illumination the light is evenly distributed.

In addition to the question of the distribution of the light, this class of lamp also has the distinct advantage of being of extremely simple design, the mechanism is, in fact, only a slight modification of their standard open-type lamp. Generally speaking, where large areas are to be lighted, such as railway and shipping yards, large factories, &c., it is not desired to have a lamp with intricate mechanism, and the simpler the better. The feeding device is most reliable in its action and is entirely unaffected by violent vibration or atmospheric conditions. The case containing the mechanism is constructed in such a manner that it is impossible for the fumes from the arc to enter, and the lamp is also fitted with a deposit preventer which prevents the globe from becoming fogged.

The carbons used in these lamps are, as stated above, of large diameter, and in consequence the risk of breakage is practically nil, whereas with thin carbons as used in "inclined" flame lamps this is an item which has to be taken into consideration.

For export work it is interesting to note that, in the event of not being able to obtain flame carbons, ordinary quality open-type carbons may be used in these lamps without any adjustment to the mechanism.

Flame Lamps for Sign Illumination.

THE accompanying sketch, which we take from the "Electrical World," shows an arrangement of a flame arc lamp sign, suggested by Mr. C. M. Axford, of Chicago, in which a pair of lamps are used to illuminate the letters, and at the same time to light the sidewalk and store front where the sign is installed. The proposed construction is made clear by the sketch. The two flame arc lamps are connected in series across a 110-volt circuit, and together consume about 1 kw. The signs should consist of black letters on a frosted background, or *vice versa*, and the sign surfaces should be inclined about 10 deg. to the vertical so as to be most effectively read

Digitized by Google

along the street. Above the sign spaces are hinged doors, through which access can be obtained to the lamps. These doors should be provided with gutters discharging at the curb line. The street end of the box should be closed, or may consist of a small sign, while the end toward the building should be left open and preferably cut away as shown, to allow light from the lamps to reach the windows and store front. For this purpose, the sign, which should be about 10 ft. in length, extending to the curb, should be mounted at least 4 ft. away from the building line, being suspended from a chain and bracket or other construction. Opal globes on the flame arc lamps will tend to improve the diffusion of the light within the sign, and to minimise the "spotting" of the letters. The use of an illuminated sign of this kind is suggested in positions where it has been the custom to hang a pair of naked flaming arc lamps in front of a store, depending on them to light the front and windows and the owner's sign. Under such conditions the extreme intensity of the lamps defeats the latter purpose, causing passers-by rather instinctively to shield their eyes from the glare. The sign proposed would, on the other hand, show the proprietor's legend to advantage along the entire street, besides lighting his sidewalk and windows at a minimum of electrical expenditure.

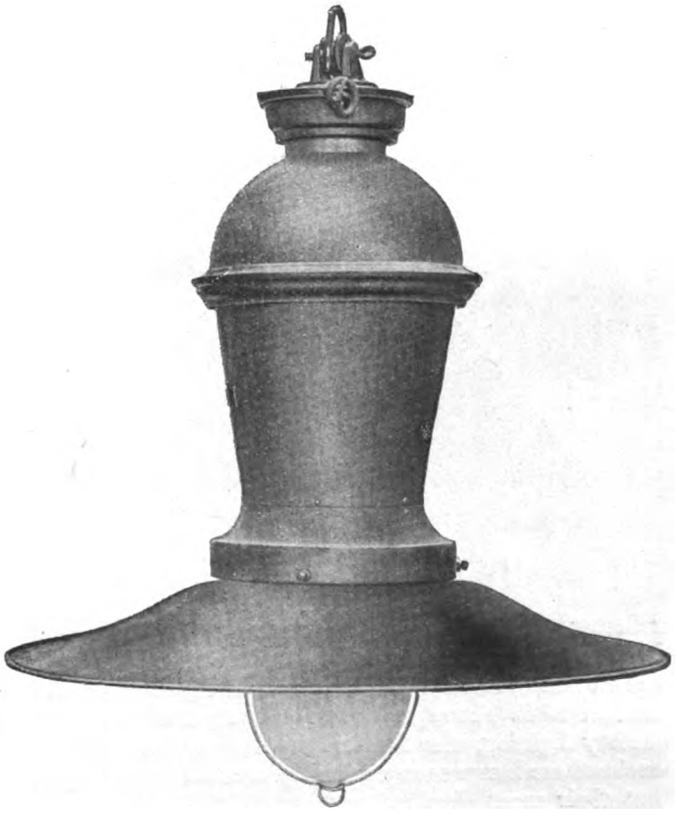
B.T.H. Intensified Arc Lamps.

THE B.T.H. intensified arc lamp, which has just been placed on the market, is the result of a continued research towards improving the efficiency of enclosed arc lamps. It embodies, it is claimed, novel features, and marks a distinct advance in arc lamp design. Carbons of small diameter are used, the result being that when an arc is formed the whole of the carbon tips, as well as the crater, become a source of light. In order to maintain a reasonably long life, the ends of two small positive carbons about 0·25 in. in diameter are brought into contact, and the arc is thereby maintained at a predetermined position in relation to the reflector. This arrangement obviates the necessity of regulating the mechanism for the upper carbon. Under normal conditions and with high-grade carbons these lamps will burn 50 to 60 hours with one set of carbons.

The lower negative carbon is actuated by the lamp mechanism which regulates the arc. An entirely new mechanism has, in fact, been designed which permits the use of these small carbons. The design embodies the following desirable features: A white light suitable for selecting and matching colours, a focusing arc (which is maintained throughout the life of carbons), steady operation, artistic appearance and high efficiencies. These lamps are designed to operate singly on circuits of 100 to 125 volts pressure, two in series on 200 to 250 volts, or five in series on 500 volts continuous current only.

The superior colour value of the enclosed carbon arc, when compared with other artificial illuminants, is a well-established fact. These intensified arc lamps when equipped with single enclosing globes and metal reflectors, and when operating at 5 amperes on 110-volt circuits, have an efficiency of approximately 1·5 watts per mean hemispherical candle-power and 1·04 watts per maximum candle-power. The maximum candle-power is at 60 deg. to 70 deg. below the horizontal. The figures of watts per candle-power include the loss in the line resistance. Apart from the high efficiency and uniform distribution obtained, the intensified arc is practically devoid of such variation in candle-power as heretofore experienced with lamps designed for use with larger carbons. Our illustration shows one type of this new lamp.



The B.T.H. Intensified Arc Lamp.

E.O.A. Arc Lamps.

A NUMBER of interesting arc lamps which are suitable for use for a number of different purposes are those manufactured by the Electric & Ordnance Accessories Co., of Birmingham. Among these are the ship's lamp, which is illustrated in Fig. 1. This shows the Victor enclosed arc lamp, which in this case is fitted with special reflector, so that when unloading at night the light from the lamp is concentrated exactly where required. The lamp shown will illuminate a circle 40 ft. in diameter when suspended 25 ft. above the deck. As regards workshop or factory lighting, the Electric & Ordnance Co. find that enclosed arc lamps are very largely used for factory lighting, but their great disadvantage is that the globes are very easily broken, and, therefore, the cost of upkeep is no small item. To reduce this as far as possible the Electric & Ordnance Accessories Co. have introduced the lamp illustrated in Fig. 2. It will be observed that the lantern is hexagonal, and, as the glass is only held in position by small copper clips, the cost of replacing a pane in the event of an accident is very small. No special globes need be kept in stock, so that a saving in storage room is thereby effected.

The above lamps are complete as illustrated. The resistance is included in the case, thus making the installation of the lamp a very simple operation. The resistance is very effectively cooled by means of the open joints in the split case. Both terminals are thoroughly insulated with mica or porcelain, and there are no live parts on the outside of the lamp.

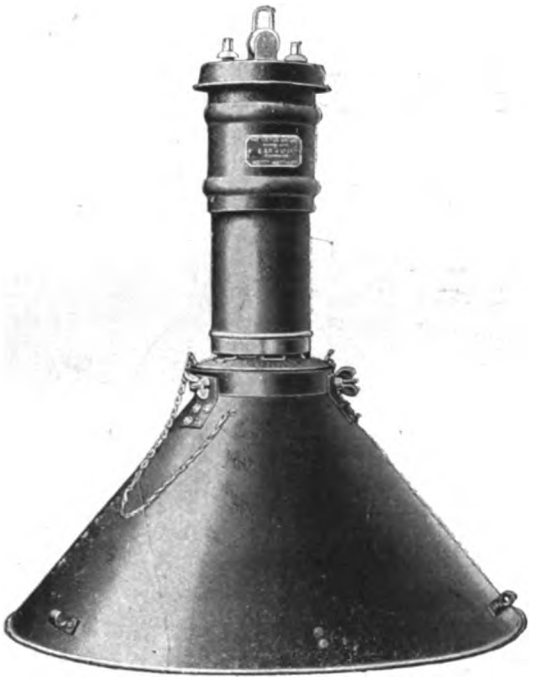

Fig. 1.—"Victor" Ship's Arc Lamp

Fig. 2.—"Victor" Lamp with Hexagonal Lantern.

In connection with the above factory lamp, we understand that the Electric & Ordnance Accessories Co. are prepared to supply a stout wire guard for use where there is little head room to suspend the lamp, or where machines are placed close together. This guard is attached by means of spring clips to the outside rim of the metal reflector, and, while not obstructing the light in any way, very effectively protects, it is claimed, the globe against breakage by ladders, poles, &c., being carelessly moved about.

Davy Sunrae Arc Lamps.

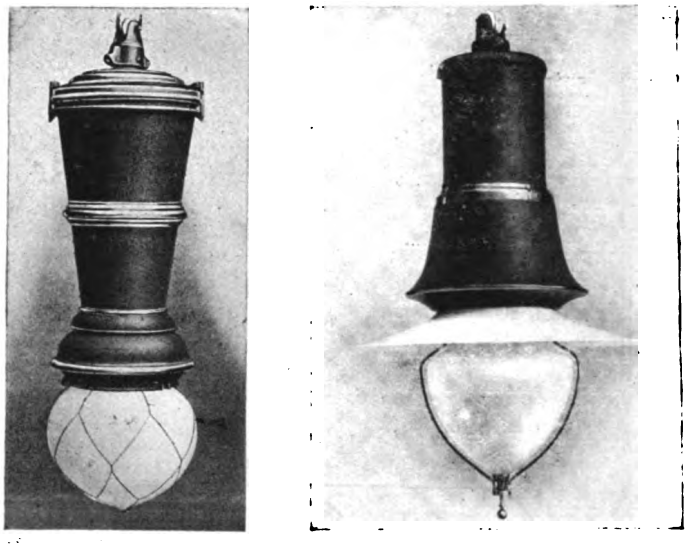
DAVY Sunræ flame arc lamps having been on the market for several years, during which time they have achieved considerable commercial success, cannot claim to be of new introduction, but rather to have established an excellent reputation over a length of time, which alone proves the merits of any kind of apparatus.

In the early days of the manufacture of flame arc lamps in this country, numerous endeavours were made by inventors and manufacturers to simplify and to get away from the complicated and clockwork mechanism of the foreign-made arc lamp, and at the same time to produce a lamp which would give longer burning hours. The four converging carbon principle upon which the Sunræ flame lamp is constructed offered one of the best and simplest solutions of this problem, as it at once possesses the advantage of a very simple form of mechanism, while securing reasonably long burning hours, equal practically to a magazine form of lamp, without the disadvantage of the complication inseparable from a lamp of the latter type.

In the Sunræ flame lamp the four carbons are held in V frames, two in the positive and two in the negative frame, and pass through a metal nozzle at the lower end of the frame until they meet and rest against each other, being fed downwards by a gravity weight, at the same time making firm electrical contact against the nozzle; thus the metallic strip through the carbon as used in some other flame lamps is rendered quite unnecessary. In the Sunræ flame lamp, too, shunt coils are entirely dispensed with, the carbon feed being quite independent of the electrical regulation of the lamp.

Another feature of the Sunræ flame lamp is a special patent form of ventilating corona, by means of which the carbon fumes are prevented from being deposited on the globe. No inner globe is used, as is common in other flame lamps, and which in practice is frequently found to become obscured and permanently discoloured, requiring renewal at frequent intervals. We give illustrations of two different types of this lamp, the longer burning pattern being built principally for street, railway, factory and similar general lighting, and the shorter pattern for purposes where long burning life is not of first importance.

We are informed that during past years large numbers of these lamps have been supplied to the Admiralty and also to some of the largest shipyards in this country, where battleships of the "Dreadnought" type are being built, which in itself is speaking testimony to their excellence.



Two Types of Davy Lamps.

Of Davy enclosed lamps it is unnecessary to make much mention as the number of years these lamps have competed successfully in the market proves their merit and good qualities where a thoroughly reliable and well-manufactured article is required. We learn that the manufacturers have recently supplied close upon 400 lamps of this type to the London & South-Western Railway for the lighting of their new works at Eastleigh.

for Flame Arc Lamps give a Light which for Brilliance, Steadiness and Reliability, is unequalled.

Conradty Carbons are well-known in the Electrical World and their adoption never fails to give satisfaction. For the effective Lighting of Public Thoroughfares, Railway Stations and Docks, Conradty's Carbons are admittedly superior to all other makes. They are of Better Quality, they give a Stronger, Steadier and more Brilliant Light, and last longer than other Carbons. Conradty's Carbons are Durable, clean in use, and as free from deposit as possible. They are made in the largest Carbon Factory in the World. They are used by the War Office, the Admiralty, General Post Office, Colonial Governments, the Railways, Dock Companies, Municipalities and Leading Manufacturers of Arc Lamps in the United Kingdom. These large users, by their constant custom, give practical expression to their high opinion of Conradty's Carbons.

NOTES.

Street Illumination.

ON another page we give an abstract of a Paper by Mr. A. J. SWEET in which he deals with street illumination as affected by glare. Although we do not care to accept without further proof the author's view as to the effect of glare upon the eyes and the reason why it causes discomfort, the conclusions at which he arrives are of considerable interest. He remarks that if a given relative illumination (as regards maximum and minimum) is to be obtained, the ratio of the distance between adjacent light units to the height of the light unit above the street must be a constant quantity, which he designates M. He finds that in America the value of M ranges from 5 up to 31, and that the value of M=15 can probably be taken as the most representative one in American practice. The great importance of this ratio does not seem to be appreciated as it should be. As the intensity of light units is increased to meet the popular demand for greater illumination it should be borne in mind that the same result is obtained with the more intense units when placed at a further distance apart, provided they are fixed at a greater height above the ground. Mr. SWEET comes to the conclusion that the best value for M is 4. This certainly seems to give an ideal illumination, but it is one that will not be reached except in large towns where the lamps are placed at a considerable height and relatively close together. Fortunately, with this value of M, it is quite possible to obtain lamps with polar curves giving only a low ratio of maximum to minimum illumination.

IN discussing the effect of glare the author has made a number of measurements, the basis of which is not entirely clear. Assuming this basis to be satisfactory, the results obtained are valuable. Thus, at an ordinary distance the presence of a light source, even of very low candle-power, in the centre of the field of vision causes a tremendous drop in visual efficiency, while a considerable increase in distance between the eye and the object produces only a small decrease in the glare. The author finds, however, that at a certain angle depending on the candle-power (the angle varying approximately between 22 deg. and 26 deg. from the line of vision) the glare effect reaches zero, although the light source is still within the field of vision. So far as we are aware this result is not in accordance with those of certain other observers. Mr. SWEET concludes that the effect of glare on the retina is local and does not cause a disturbance when the spot affected is sufficiently separated from the retinal image of the object under inspection. Based on these observations, Mr. SWEET concludes that the light instrumental in causing glare comes entirely from those rays whose polar angles are above 60 deg. with the nadir. Consequently, the light between the angles of 60 deg. and 80 deg. should be partially or wholly suppressed. There is a good deal of truth in the statement that if the glare limit is exceeded at all it will almost of necessity be exceeded excessively, and we fear that in many cases glare must remain with our present systems of illumination, for the simple reason that the local authorities concerned would not be able to afford its elimination. There is also much truth in the statement that the ordinary citizen of to-day uses, in his ignorance, the very defect itself—namely, the glaring character of street illumination—as a measure of its excellence. Possibly this is why our gas friends place horizontal reflecting surfaces above their mantles.

Tramway Comparisons.

MUNICIPAL tramway committees have frequently been criticised for handing over to the rates considerable sums of money from the profits of their tramway undertakings, sometimes without having made adequate provision for depreciation. The desirability of paying over large amounts for the relief of the rates, even where this is amply justified by the financial position of the undertaking, is open to question. No two opinions, however, can be held as to the necessity for a reserve fund sufficient to meet future renewals of track and plant, although opinions may differ as to what allowance can be considered adequate for this purpose. In this connection comparisons between the allowance made in the case of municipal undertakings and that in company-owned tramways can scarcely be regarded as in any way convincing. In his Presidential Address last week to the Municipal Tramways Association, Mr. C. J. SPENCER mentioned that whereas in the case of municipal tramway undertakings a total sum equivalent to 3½ per cent. of the whole capital outlay was paid last year into the sinking funds and reserve and renewals funds, tramway companies only put aside for depreciation, obsolescence, &c., an amount equal to 1·05 per cent. of their capital. On these figures Mr. SPENCER considered that municipal tramways were, as a whole, commercially sound.

WE think, however, that, apart from the fact that a sinking fund should not be compared with a provision for depreciation, such comparisons by no means justify the policy of many municipal authorities in regard to depreciation and reserve funds. Municipal trading should be as little speculative as possible; and it is therefore desirable that municipalities should err on the side of an ample provision for reserve and depreciation in the case of their electricity and tramway undertakings. Unfortunately, however, this is not often the case. From our analysis of the Bradford Corporation tramway accounts elsewhere in this issue, it will be seen that whereas a sum of £20,000 has been handed over for the relief of the rates, the contribution to the reserve and renewals fund amounts to £12,365. This latter sum only represents a little over 0·5d. per car-mile, and can scarcely be regarded as in any way an adequate provision for depreciation, especially as many other undertakings are now finding it desirable to provide for possible future requirements on a much higher scale than this figure. In support of the adequacy of the present contribution, Mr. SPENCER, in his annual report, compares the provision of £12,365 for reserve and renewals with the sum of £8,708 set aside last year in the case of a company-owned undertaking of similar size and working under similar conditions to those at Bradford. This, however, cannot be regarded as justification of the policy adopted, and we think that the Committee would be well advised in future to build up the reserve and renewals fund, which at present only amounts to £44,006, the capital expenditure totalling £930,114, even if this policy involves a certain amount of unpopularity, due to the ratepayers not benefiting to so large an extent from the tramway "profits." With the above exception, the annual report of Mr. SPENCER is very satisfactory, and shows that good progress is being made by the Bradford tramways, the success of "through-running" between Bradford and Leeds being particularly noteworthy.

Town Planning and Tramways.

THAT a municipality should not, as a general principle indulge in speculative transactions will, we think, be universally admitted, and we fear that if the suggestions put forward by Mr. A. BAKER, in his Paper read last week before the Municipal Tramways Association, were extensively adopted, they might lead to unfortunate results for the ratepayers in the case of a too enterprising local authority. The suggestion to which most exception is likely to be taken is that in regard to speculation in land outside the municipal boundary; but the question as to whether a tramway should be laid down when the prospective traffic is insufficient to make the undertaking a financial success, at any rate in its early days, will also certainly arouse much discussion. There is no doubt that the housing problem has been rendered easier of solution by the provision of cheap tramway facilities, and the tendency for suburban districts to develop in proximity to electric tramway routes is very marked at the present time; but proposals for the extension of tramways into practically undeveloped localities would require most careful consideration, and we think that in such cases a railless traction scheme should undoubtedly be preferred. If future developments warranted the laying down of a tramway track the railless vehicles could then be transferred to other routes. In regard, however, to the benefits likely to result from a well-planned scheme of thoroughfares with a minimum width of 91 ft., there can be little diversity of opinion, and the location of the tramways in the centre of such a road would undoubtedly facilitate the maintenance of a much higher average speed. In this connection, the suggestion of one speaker during the discussion on Mr. BAKER'S Paper, that in the ideal scheme the tramways should run up and down the sides of the main road, will not, we think, meet with much support, for even with cars running at the usual speeds a tramway track close to the footpath is dangerous, to say nothing of the inconvenience caused to vehicles standing at the side of the road. It is certainly important, however, that tramway requirements should be taken into account in the laying out of future roads, for the capital expenditure which has been incurred in widening streets and altering curves has often proved a considerable burden to both municipal and company tramways, more especially to the latter.

Submarine Cable Concession.—H.M. Consul at San José (Mr. F. N. Cox) states that a contract has been made between the Foreign Minister and a *British subject* for the establishment and working of a submarine telegraph cable between Colon and Limon. The concessionaire has the exclusive right for 15 years of working a cable office in the Republic, and during that period may import duty free all materials, instruments and supplies required for use in his enterprise. He is also granted the right to establish one wireless telegraph station in connection with the cable station. Work must be begun within nine months from date of approval of the contract, and be completed within 18 months. The "Board of Trade Journal" states that the name of the concessionaire may be obtained by British firms on application at 73, Basinghall-street, London, E.C.

Wireless Telegraphy and Kites.—We understand that Mr. Marconi, who is at present on his way to Buenos Ayres, has during his voyage been conducting some interesting experiments on the use of kites in wireless telegraph work. From a message that has been received at the offices of the Marconi Wireless Telegraph Co. in London, it appears that, using a kite to support the antenna, Mr. Marconi has been able to transmit and receive "strong" signals over a distance of 3,500 miles. With the apparatus installed on the "Principessa Mafalda," of the Italian Lloyd line, the ship on which Mr. Marconi is travelling, the maximum range during daylight would be, using the mast to support the antenna, about 1,500 miles. It will thus be seen that a distinct increase in range can be obtained, even taking into account the fact that a special valve receiver was being used (this would probably increase the range about 10 per cent.), and that Mr. Marconi's well-known skill as an operator was applied. We understand that the experiments will be continued, though they were temporarily suspended owing to a high wind making it difficult to keep the kites up. The possibility of thus using kites seems to point to an easy way of increasing temporarily the range of the ship's instruments in case of need.

Trunk Line Electrification in Austria-Hungary.—In a Paper read at the Berne International Railway Congress, an abstract of which appears in the "Electric Railway Journal," A. Hruschker, of the Government Railway Engineering Department, presented statistics on electric traction developments in Austria-Hungary. These show that the following electric trunk line railways were in operation at the end of 1909 :—

Line.	System and voltage.	Length Opened in miles.	in
Tabor-Bechyn	Three-wire c.c. 700 volts	14·50	1903
Innsbruck-Fulpmes	Single-phase, 2,500 volts	11·35	1904
Bludenz-Schruns	Continuous, 500 volts	8·06	1905
Vienna-Baden	Single-phase & 550 volts c.c.	17·95	1907
Bruneck-Sand	Continuous, 500 volts	9·52	1908
Neumarkt-Waizenkirchen	„ „ „	10·06	1908
Trient-Malé	„ 800 „	37·25	1909
Total		103·69	

In addition there are some 16 extended electric tramways and mountain railways, aggregating about 94 miles in length. Two additional trunk lines are under construction for electrical working, aggregating 87·6 miles, viz., Vácz-Rákospalota, 31 miles, being equipped with 15 cycles single-phase at 10,000 volts, and St. Pölten-Mariazell-Gusswerk, 50 miles, 2 ft. 6 in. gauge, being equipped with 25 cycles single-phase at 6,000 volts. In 1906 a branch of the Austrian Government State Railways was formed to study the subject of the electrical equipment of the different lines. An examination of the available water powers was made and 11 schemes, with an aggregate capacity of 140,000 H.P., were worked out. Calculations were also made of the application of this power to 2,722 miles of track. An official report on the results will appear shortly. Those lines to which especial attention has been given are in the neighbourhood of Trieste and Innsbruck. While no official decision has been reached in the selection of a system the speaker favoured the single-phase. In this connection he stated that the only other system worth serious consideration was the three-phase, whose principal advantage was the smaller weight of car for the same output. Plans have already been prepared by the Austrian Government engineers for the equipment of certain of its railway lines with the single-phase system at 15 to $16\frac{2}{3}$ cycles and 10,000 volts. The Hungarian Government has also considered electrification. It has plans prepared for the equipment of one line with three-phase equipment and has decided to use single-phase on another, but has not definitely settled upon any standard system.

The Late Harry W. Cox.—A grant of £150 has been made by the Prime Minister to Mrs. Cox, widow of the late Mr. Harry W. Cox, whose death resulted from his pioneer work on X-rays.

Trans-Atlantic Cables.—Two notices appeared in Tuesday's "Gazette" to the effect that application has been received by the Board of Trade from the American Telegraph & Cable Co. and the Western Union Telegraph Co. for the renewal of their licence to maintain and use upon the foreshore and bed of the sea at Sennen Cove, Cornwall, two telegraph cables from America; and that an application had been received by the Board from the Western Union Telegraph Co. for a licence to lay down and maintain upon the foreshore and bed of the sea at Sennen Cove, Cornwall, two additional telegraph cables from America. All persons interested are to take notice that 28 days after September 24th the Board will proceed to consider the applications, and in the meantime they will receive any objections which may be made thereto.

Magnetic Alloys Formed from Non-Magnetic Materials.—At the meeting of the Institute of Metals at Glasgow last week a Paper dealing with investigations carried out chiefly on ternary alloys consisting of copper, manganese and one of the elements aluminium, tin, bismuth and antimony, was read by Mr. A. D. Ross. Details were given as to the method of preparing, analysing and testing the materials. All the groups showed fair magnetic quality, but the most interesting were the ternary alloys containing aluminium and tin respectively. Some of the former were, under small magnetising forces, much more magnetic than cobalt, and had little coercive force. The tin alloys were less permeable, but exhibited greater hysteresis. Most of the alloys improved in magnetic quality when they were annealed for a short time at a moderate temperature—150°C. to 200°C. Prolonged annealing invariably had an adverse effect, the hysteresis loss increasing rapidly with time. The behaviour of the alloys on cooling to the temperature of liquid air was peculiar and characteristic. For low and moderate fields the process resulted in general in a decided increase in susceptibility, whereas almost all other magnetic materials were rendered less susceptible. Quenching the alloys at a red heat diminished the permeability. The point of greatest interest was that it also resulted in greatly reducing the hysteresis loss. In fact, nothing was known which approached closer than a quenched copper-manganese-aluminium alloy to the ideal magnetic material which should be strongly magnetic and without hysteresis. The quenched alloys were in a somewhat unstable condition, their permeability gradually increasing towards its former value, but with little or no augmentation of the coercive force. These alloys, while of great theoretical interest, have not yet found practical application. They are hard and brittle, very sensitive to thermal changes, somewhat unstable and apt to segregate. The magnetism of the copper-manganese-aluminium alloys is apparently due to the formation of solid solutions of the compound Cu_2Al with Mn_2Al, or possibly with manganese. Similar solid solutions probably occur in the other ternary magnetic alloys.

Electric Railway for Ore Transportation in Brazil.—According to the "Electric Railway Journal," construction work was recently begun on the first of two 25,000 kw. hydro-electric generating stations on the tributaries to the Doce River, in Brazil, which will furnish energy for an electric railway, 400 miles in length, between Victoria and Itabira, in the State of Minas Geras. The region penetrated by the new electric railway is a mining country producing large quantities of iron ore, the transportation of which to the coast will be the principal business of the new line. In building the line, about 250 miles of existing narrow-gauge steam roadbed will be utilised, the track being converted to standard gauge. Our contemporary states that the railway is being constructed by a British company which owns the iron ore workings, and that the electrical equipment will be of English manufacture.

The Operation of Electrical Commercial Vehicles.—On August 12th 69 motor trucks of all sizes, powers and types participated in the "North American's" commercial motor

Digitized by Google

vehicle run from Philadelphia to Atlantic City, *via* Camden, and return. The "Electrical World" mentions that nine of the vehicles were electrically driven, and these, although competing out of their class, and taken from active service without special preparation, made several good records. The distance between Camden and Atlantic City is 60 miles, and the return run was made on August 13th. According to the rules governing the contest, each truck was weighed-in, both empty and full, and in order to facilitate matters three weighing-in stations were established. The schedules of speeds established were as follows: Class A, 1½ tons and less, 12 miles per hour; class B, 3,001 lb. to 5,999 lb., 10 miles per hour; class C, 3 tons and over, 8 miles per hour. In reckoning the results a penalty of one point was imposed for every half minute a car departed from the schedule, and the awards were based on the ability of cars to keep to the time schedule and on the smallest consumption of energy. The actual load carried by the vehicle over and above its own weight formed the basis of the computations. The energy consumed was charged at a rate of 2d. per kw.-hour. The results were as follows:—

CLASS A.

Type.	Weight empty, lb.	Load carried, lb.	Penalties.	Kw-hrs. used.	Cost per ton-mile.
Commercial truck	5,350	2,000	6	41·830	0·65d.
Commercial truck	5,050	2,000	14	38·399	0·60d.
Commercial truck	3,650	1,500	0	30·268	0·65d.
*General vehicle	4,980	2,000	8	30·824	0·51d.

CLASS B.

*General vehicle	6,700	4,000	15	42·336	0·35d.
Commercial truck	6,540	4,000	93	57·935	0·45d.
Commercial truck	7,200	4,000	144	†	†

CLASS C.

*Commercial truck	10,250	7,000	0	83·190	0·35d.
General vehicle	9,562	7,000	30	79·776	0·40d.

* Winner. † Meter defective.

The nine vehicles came within 100 per cent. of each other on the cost per ton-mile, while those of a single manufacturer came within 43 per cent. on the cost per ton-mile. The gasoline vehicles showed a difference of 867 per cent. Gasoline vehicles of the same manufacture showed a difference of 143 per cent. The lowest cost per ton-mile for the gasoline vehicles was 0·35d. and the highest 3·4d. Every electric vehicle finished the run, whilst 11 per cent. of the gasoline vehicles and seven trucks failed to finish.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Messrs. W. H. Eccles and A. J. Makower contribute an article on "The Efficiency of Short-Spark Methods of Generating Electrical Oscillations."

We give abstracts of the remaining Papers read at the Annual Conference of the Municipal Tramways Association, at Bradford, last week—viz., "The Comparative Durability of Brake Shoes and Tyres," by J. W. Dawson; "Tramways in Relation to Town Planning," by A. Baker; and a report on "The Lubrication of Car Bearings," the last being the work of a sub-committee of the Association.

We give an abstract of a report on "The Use of Meters on Tramcars," by Mr. Battes, of the Frankfort tramways, read at the recent meeting of the Union Internationale de Tramways et de Chemins de fer d'Intérêt local.

A new system of car lighting has been introduced by Messrs. C. A. Vandervell & Co.

We give an analysis of the accounts of the Bradford Corporation tramways for the year ended March 31st last.

Acton Council have referred back a recommendation for the transfer of their electricity undertaking to the Metropolitan Electric Supply Co. Particulars of the proposed transfer are given in another column.

The Electricity Committee of Leicester Corporation have finally decided not to appeal against the recent injunction restraining them from carrying on their electric wiring and fittings department.

Rotherham Corporation have decided to promote a bill to authorise them to equip railless trolley omnibuses, and for additional powers for electricity supply, &c.

A 50-years' concession for the supply of electricity in Constantinople has been awarded to a group composed of Hungarian and French syndicates.

At the meeting of Dick, Kerr & Co. yesterday (Thursday) the chairman, Mr. John Kerr, said the past year's trade had been disappointing, but a period seemed at hand when there would be great expansion in electrical work at home and abroad. The Company have arranged to manufacture steam turbines under the Bergmann patents.

INSTITUTIONS AND SOCIETIES.

Municipal Tramways Association.—At the annual general meeting held at Bradford on Friday last, Mr. J. Dalrymple, general manager of the Glasgow Corporation tramways, was elected president, and Mr. H. E. Blain, of West Ham, vice-president. Next year's meeting will, therefore, take place at Glasgow.

Victorian Institute of Electrical Engineers.—The first annual dinner of the Victorian Institute of Electrical Engineers took place on August 19. Among the visitors were Dr. Alex. Graham Bell and the Australian Postmaster-General, and their health was proposed by the president, Mr. A. H. Jackson.

Dr. BELL, in replying, gave some interesting reminiscences of the history of the telephone, and said the first telephone was erected by him at Brantford (Ont., Canada) in 1876. The wire was tacked along a wooden fence from his father's house to the corner of Mount Pleasant-road and there connected with a telegraph wire leading into the town. A remarkable occurrence took place in 1877 when the first commercial telephone was being put up. Some friends of his at Rhode Island put up a telephone from one house to another as an experiment, and persons who listened at one end of the line heard a concert which was afterwards found to have taken place in New York City, 200 miles away.

The POSTMASTER-GENERAL (Mr. Thomas), in proposing "The Electrical Profession," said he had the pleasure lately of fixing matters so that if the Government were in power for the next two years it would be found to have spent more money on telephones than had been spent in Australia during any previous two years. He hoped a great deal of telephone material would be produced in Australia before long. He was determined to make their telephone service the best that could be got.

The Association of Mining Electrical Engineers.—A special meeting of engineers interested in the application of electricity to mining will be held at the Royal Hotel, Dunfermline, to-morrow (Saturday) at 6 p.m. The object of this meeting is to consider the inauguration of a branch of the above Association in the East of Scotland, and to appoint a local president, a committee and other officers, in order to further the objects of the Association in that district. A representative of the council from one of the other established branches will attend the meeting to give any information or particulars as to the work of the Association.

Smithsonian Institution.—The general appendix to the annual report for the year ended June 30, 1908, of which we have recently received a copy, contains a selection of miscellaneous memoirs of interest to the collaborators and correspondents of the institution, teachers, &c. Among the many Papers and lectures reprinted we notice the following of electrical interest: "Wireless Telephony," by Prof. R. A. Fesseaden (a Paper read two years ago before the American Institute of Electrical Engineers); "Phototelegraphy," by H. Armagnat (translated from the "Revue Scientifique"); "On the Light thrown by Recent Investigations on Electricity on the Relation between Matter and Ether," by Sir J. J. Thomson (the Adamson lecture delivered at Victoria University, Manchester, in November, 1907); "The Life and Work of Lord Kelvin," by Prof. S. P. Thompson, (the first Kelvin lecture, delivered before the Institution of Electrical Engineers); and "The Work of H. Becquerel," by A. Broca (translated from the "Revue Générale des Sciences Pures et Appliquées").

ARRANGEMENTS FOR THE WEEK.

MONDAY, Octo er 3rd

SOCIETY OF ENGINEERS.

7:30 p.m. Meeting at Caxton Hall, Westminster. Paper on "Current Professional Topics," by Mr. H. C. Adams.

Digitized by Google

BRADFORD CORPORATION TRAMWAY ACCOUNTS.

The tramways undertaking of the Bradford Corporation, although not one of the largest, is certainly one of the most interesting in this country. This partly arises from the fact that the undertaking has always been to the fore in adopting innovations, both as regards apparatus and methods of working. Thus, it will be remembered that the problem of adapting a car to operate on two different rail gauges was first successfully solved in connection with the "through service" between Bradford and Leeds. Again, the Corporation have applied for powers to adopt the trackless trolley system on a route from Laisterdyke to Dudley Hill, as a result of the favourable report of the deputation of the Tramways Committee that paid a visit to the Continent last December to inspect the various systems of railless traction. The advantages of car meters for checking the energy consumption, of a parcels department, and of electrically operated point controllers were also early appreciated by the management; whilst the practice of carrying blind persons free of charge is a striking innovation.

The annual report for the year ended March 31, 1910, of Mr. C. J. Spencer, general manager of the undertaking, records greatly improved results compared with those of a year ago. This will partly be evident from the fact that 50,518,813 passengers were carried, compared with 47,660,011 in 1908-9, an increase of 6 per cent. The total revenue amounted to £259,696, or £15,462 more than in the previous 12 months; whilst, as the car-mileage only increased by 1·1 per cent. a much higher revenue per car-mile was obtained. The total number of car-miles was 5,436,529, the number of miles of route being 54·8.

The traffic mentioned above represented 149 journeys per annum per head of population, the average fare paid per passenger being 1·167d., and the average revenue per car-mile amounting to 10·977d., as against 10·456d. a year ago. A feature of the traffic records is the large number of "through tickets" between Bradford and Leeds. "Through running" only commenced on June 7, 1909, but 105,569 6d. "through tickets," and 5,054 children's 3d. tickets were issued by the Bradford tramways department, and 107,463 by the Leeds tramway department. The service has proved of great public convenience, and has worked very smoothly. As 8d., 10d., and 1s. tickets are also issued over the Yorkshire Woollen District Tramways, it is perhaps surprising that the average fare per passenger is not greater than 1·167d. The 1d. fare, however, is the controlling factor, about 80 per cent. of the total traffic coming under that heading. The average distance covered by this fare is 1·61 miles in the case of ordinary passengers, and 4·03 miles on all cars before 8 a.m. An interesting feature of the statistics is that 43,852 blind passengers were carried free of charge.

In regard to power consumption, 10,076,417 units were used, representing 1·85 units per car-mile, compared with 1·88 units in the previous year. The cost of the power worked out at 2·073d. per car-mile. The average number of cars in use for a 15-hour day was 136, the total number of cars in stock being 239.

Turning now to the accounts it is seen that the total expenditure amounted to £170,699, compared with £170,196 in 1908-9. Against this, however, must be placed an increase of £15,462 in the receipts, so that a net profit of £32,365 is shown for the year's working, as compared with £15,318 a year ago. The contribution of £20,000 to the relief of the rates, however, may seem open to criticism. From the point of view of whether a sufficient sum is being set aside for depreciation, Mr. Spencer includes in his report an extract from the last published Board of Trade returns the figures relating to a large successful tramway company in the South of England working under similar conditions to those at Bradford and of similar size. The figures are set out herewith.

Mr. Spencer says it will be noted that with receipts approximately the same and with very similar expenditure, the gross profit of each undertaking is fairly comparable. In the case of the Company Tramway, £76,639 of the gross profit of £85,347 is disbursed in dividend, the balance of £8,708 being passed forward to the reserve fund for depreciation purposes. In the case of Bradford, after the gross profit of £91,613 is arrived at, £22,407 is paid for interest, which in some senses represents dividend, £12,365 is passed forward for depreciation, and in addition thereto £30,454 is paid to the Sinking Fund and a sum of £20,000 is paid over in relief of rates. Mr. Spencer remarks: "It is obviously fair to assume that if the large Company concern mentioned, with a similar capital and similar conditions, is adequately meeting depreciation with £8,708, then Bradford must be exceedingly generous when it puts by for the same purpose £42,819." Comparisons of this nature, however, we consider are not very convincing.

Interest	22,407		Dividend 76,639
Repayment of debt, or sinking fund	30,454	..	nil.
Rent of leased lines, &c.	4,137	..	nil.
Reserve, including Depreciation and Renewals fund.	12,365	..	8,708
Other matters, including income tax, balance carried forward, &c.	22,250	..	nil.

The total working expenses per car-mile work out at 7·149d. as against 7·221d. last year, and are the lowest on record for the undertaking; whilst the figure of 10·977d. for traffic and sundry revenue is the highest. This condition of affairs is certainly most gratifying. In regard to details of the expenses, it will be noted that only one item in the traffic expenses shows an increase, namely, the cost of cleaning, salting and sanding track. The small increase is wholly accounted for by the severity of the winter and the heavy expense incurred in keeping the track open for traffic during the snowstorms. Mr. Spencer points out that this is a great convenience to the public generally, as the tramways open up the main routes for vehicular traffic.

In regard to the parcels department, this has earned £8,169 as against £7,350 in the previous year, the net profit being £1,741 and £1,028 respectively. The number of parcels handled was 675,719, an increase of 70,406 over that of 1908-9.

We give below an analysis of the accounts for the year ended March 31st last, together with the cost per car-mile, the latter figure also being tabulated for the previous year to facilitate comparisons:—

		Cost per car-mile. 1909-10.	1908-9.
Traffic Expenses.			
Superintendence	£331	0·01d.	0·01d.
Wages of drivers and conductors	44,384	1·96d.	1·97d.
Wages of other traffic employés	2,425	0·11d.	0·11d.
Cleaning and oiling cars	6,154	0·27d.	0·28d.
Cleaning track	2,225	0·10d.	0·09d.
Fuel, light and water for depôts	2,032	0·09d.	0·10d.
Ticket check	2,927	0·13d.	0·13d.
Uniforms	1,980	0·09d.	0·09d.
Miscellaneous	1,542	0·07d.	0·07d.
Total Traffic Expenses	£64,000	2·83d.	2·85d.
General Expenses.			
Salaries	£2,779	0·12d.	0·12d.
Administration and establishment charges	750	0·03d.	0·03d.
Store expenses	366	0·02d.	0·02d.
Rents	758	0·04d.	0·04d.
Rates and taxes	8,840	0·39d.	0·44d.
Printing and stationery	550	0·02d.	0·02d.
Fuel, light and water for offices	242	0·01d.	0·01d.
Compensation	1,740	0·08d.	0·09d.
Insurance	257	0·01d.	0·01d.
Miscellaneous	2,278	0·10d.	0·08d.
Total General Expenses	£18,560	0·82d.	0·86d.

* The expenditure for Bradford does not include renewal cost of permanent way. The Board of Trade figures do not show whether the Company's return does or not.

THE COMPARATIVE DURABILITY OF BRAKE SHOES AND TYRES.*

BY J. W. DAWSON.

(Assistant Engineer, Bradford Corporation Tramways.)

Summary.—The author gives particulars of tests on brake shoes, to ascertain the durability of the various types and their wearing effect upon steel tyres.

Many opinions have been put forth respecting the wearing effect upon steel tramway tyres by brake shoes. Until quite recently no systematic tests appear to have been carried out to demonstrate the relation between the material of the shoe and its effect upon the tyre, and to indicate which type of shoe should prove most economical in use. The amount appearing in car repair and maintenance costs for the upkeep of brakes and wheels is quite sufficient to warrant a very close consideration of the inter-relation of these two indispensable parts of the equipment.

The investigations recorded in this Paper were undertaken with the object of ascertaining the comparative durability of the various grades of brake shoes used on tramcars in this country, together with their wearing effect upon steel tyres, recording at the same time any observed features or properties of the shoes under test which appeared to have a bearing upon the durability of the shoes and tyres. Twenty different grades of shoes have been tested (particulars of each are given in the Paper) and were chosen to cover the range of shoes in actual use in this country.

* Abstract of a Paper read last week at the Conference of the Municipal Tramways Association.

Service Tests.—Comparison of the life of brake shoes and tyres on one tramway with those obtained on other tramway systems is of very little value, so many factors operating which entirely vitiate the results, such as difference in gradients, nature of the road grit, track brakes, speed, average number of stops per mile, use of rheostatic or magnetic brakes for service stops, &c.; but comparison of various grades of shoes can with advantage be carried out on the cars of any one system. The results will not, of course, be of quantative accuracy, but will give an indication of the difference between, say, a standard brand of shoe and other types used at the same time. For purpose of comparing results obtained with shoes on tramcars under service conditions with those obtained in the works laboratory under uniform conditions, tests have been made by this method. In service tests one particular make of shoe was adopted as the standard for comparison. One standard shoe and one with which it is to be compared were fitted to the wheels at one end of the car, and similar shoes fitted at the other end, the same grade shoe being at diagonal positions on the truck, one of each grade of shoe thus acting upon each axle and making the retarding effort per axle equal, the shoes being accurately weighed before fitting. The car is then run until some of the shoes are worn out; they are then taken off and again weighed. The amount of metal worn from the test shoes to that worn from the standard shoes will be in inverse proportion to their durability when run with equal pressures upon each shoe; but it must be particularly noted that the shoes with the highest coefficient of friction will have done the most work, so this method of testing is decidedly favourable to shoes having the lowest coefficient of friction. If the circumferences of the tyres are measured before and after the test, it will be ascertained which shoes have caused the greatest tyre wear. The average of measurements from several cars should be taken. Results obtained by this method are shown in the table herewith.

Service Tests of Shoe and Tyre Wear.

	Wheels. Miles per ⅛th radial wear.			Shoes. Miles per lb.		
	Test shoe.	Standard.	Ratio.	Test shoe.	Standard.	Ratio.
Cast white iron	6,060	10,954	0·55	966	447	2·16
Cast iron with white iron inserts	12,665	9,900	1·30	296·7	722	0·41
Cast soft grey (hardness 41)	14,307	5,830	2·45	214	834	0·26
Cast soft grey (hardness 46)	14,630	8,955	1·63	181	5,332	2·94

Comparison of these tests with those obtained with the test apparatus under laboratory conditions proves that the results obtained on the latter correctly indicate the comparative wearing properties of shoes and tyres when run under ordinary service conditions, with the exception of the first, of which the characteristics of the metal appeared to produce seizing readily. Examination of the table shows very clearly that by this method of comparison the life of the standard shoe varies with the coefficient of friction of the shoe with which it is run. Differences of tyre wear by various grade shoes are very noticeable. The author is of opinion that one cause of the differences in wheel diameters, so prevalent on tramcars, may be the use of brake shoes of uneven grades.

Another method is to fit up a number of cars with test shoes, keeping record of their mileage and loss in weight, also records of standard shoes on similar cars running concurrently on the same route and schedule if possible. This test, to be of value, should extend over a long period, in order that running conditions may reach an average.

Adjustable Leverage.—To obtain accurate comparative results of shoe wear and differences of tyre wear, it is absolutely necessary that each shoe should give the same retarding effort. To do this the pressure applied to each shoe must be in inverse proportion to its coefficient of friction. This has been secured by means of the brake gear designed by the author and illustrated on p. 1011. In use, shoes of equal grade are fitted on each pair of wheels. The leverage ratio of the brake gear is adjusted by means of the links between the supplementary brake beams, in proportion to the respective coefficient of friction of the shoes, thus obtaining from each pair of shoes the same retarding effort.

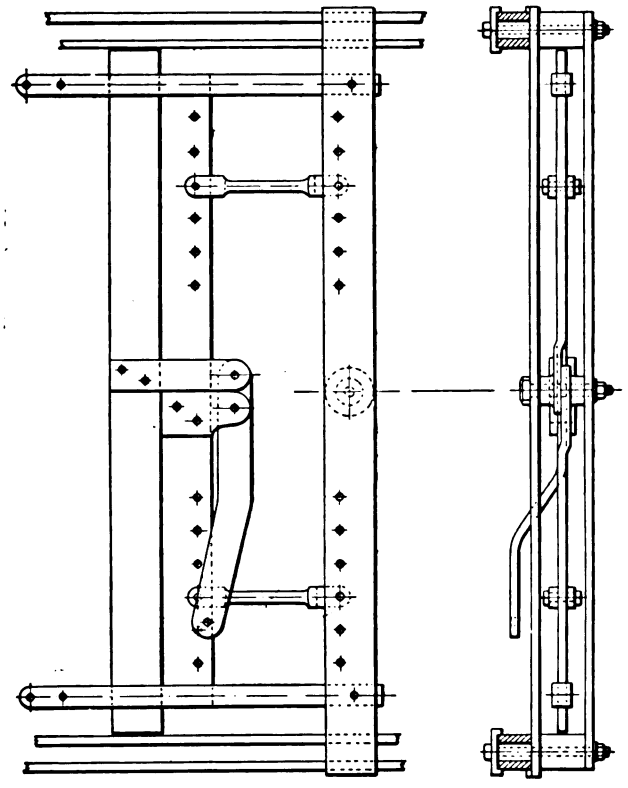
To form an accurate estimate of the value of a shoe from results of road tests is practically impossible. To obtain standard and comparable results it becomes necessary, therefore, to carry out the tests with a true wheel revolving at a constant rate of speed with steady braking load, and a uniformly clean surface. While these conditions are far removed from those existing on the road, the author submits that the results are quite in accordance with those

Digitized by Google

obtained on service cars, and have the great advantage that shoes may be tested at any period of their life—their characteristics and subsequent value determined in a few hours.

Laboratory Tests.—For the purpose of carrying out tests under known conditions, a 30 H.P. tramways motor has been installed, driving through the usual single reduction gear an axle upon which is mounted a wheel-centre with steel tyre. The shoe is pressed upon the wheel by means of a lever carrying at one end a pan, which can be loaded with weights, and at the other an adjustable radius rod and a dynamometer for registering the pull upon the shoe. A pulley running upon the tread of the wheel drives a speed and mileage indicator. (The apparatus is similar to that used in connection with the brake shoe tests for the Municipal Tramways Association Brakes Sub-Committee, and illustrated in their report.)

For measuring tyre wear an apparatus designed by the author is used. It consists of a means for determining the difference of volume reduction over a pre-determined area of the tyre surface, this by calculation giving the total amount of tyre removed. The apparatus comprises a die with means for forcing its inner face to a fixed radial distance from the centre of the wheel, the distance being determined by the outer faces of the die being in contact with two side faces of the tyre. In operation a piece of ductile metal (lead) is placed under the die which is then forced on to a turned face on each



ADJUSTABLE LEVERAGE-RATIO BRAKE GEAR.

side of the wheel, the inner face of the die will thus be a fixed distance from these faces, and the thickness of the lead will be equal to the distance between the inner face of the die and the surface of the tyre, the lead following exactly the conformation of the wheel face. In the die are two small recesses, which form projections on the backs of the test pieces. These projections enter into holes in the block of the cutting die, ensuring accurate cutting of the test pieces. After being removed from the die, the test pieces are cut to 0·5 in. wide, a test piece being taken at the beginning and close of each run. These cut pieces are weighed on a chemical balance, the difference in weight of the two pieces equals the weight in lead of the volume of tyre removed per 0·5 in. of the tyre circumference, and can be calculated into equivalent weight of steel worn off the tyre. The tread portions of the shoes only are used, the flanges being removed in order to prevent uneven readings due to side pressure or wedging of the wheel flange in the groove of the shoe, the wearing face of the wheel being flat, the shoe bearing upon the centre portion only.

The particulars of the test apparatus are as follows:—Wheel tyre 33 in. diameter by 3⅛ in. wide, made from Siemen's open hearth acid steel, test piece from a tyre of the same cast giving 56 tons maximum stress, 14 per cent. elongation in 2 in. 30 H.P. series traction motor, equivalent speeds during tests, 10 miles per hour. The adjustment in the "wet" tests was such as to give a pull on the shoe equal to one-fourth of the retarding force required to balance the acceleration due to gravity of a four-wheel 10-ton car descending a 1 in 9 gradient at a speed of 10 miles per hour. If applied to the car on the level, this would be equal to a retardation at the rate of 3·6 ft. per second per second, and would stop the car from 10 miles per hour in 4·09 seconds in a distance of 30 ft., neglecting any retardation due to the friction of the car or other forces. In the "dry" tests the weight on the shoe was one-half of that used in the "wet" test. The "wet" tests lasted 4 to 5 hours, and the "dry" tests 2 hours.

Mr. J. A. Panton has recently stated in his Paper on "Brake Shoe Standardisation," that "it is cheaper to wear out brake shoes than wheels, which are more costly." The present author finds the cost of shoes and tyres to be about equal, as follows:—

Shoes.

Four shoes, 112 lb., at £8. 10s. per ton*	£0	8	6
Scrap, 56 lb., at £2. 10s. per ton	0	1	3
	0	7	3
Labour, 13 hours at 6d.	0	6	6
Total cost 56 lb. useful metal =	£0	13	9
= Cost per lb. useful metal = 2·94d.			

Tyre.

Weight rolled blank	290 lb.	Cost	£1	12 4
Removed by boring	10 lb.			
Profile turning	5 lb.			
Half life re-turning	20 lb.			
Scrap weight	87 lb.			
Total scrap weight	122 lb. at £3 per ton =		0	3 3·21
Net useful metal	168 lb.		£1	9 0·79
Labour.—(Boring 2¾ hours, turning 2¼ hours, re-turning half life 2¼ hours, shrinking ¼ hour, removing from centre ¼ hour) 7¾ hours at 34s. for 53 hours. =			£0	4 11·64
Gas for heating			0	0 1·5

Standing Charges.

Boring mill or lathe, £250 at 15 years	£16	13	4
Average interest at 4 per cent.	5	0	0
Tools and repairs at 2 per cent	5	0	0
	£26	13	4

Taking 50 weeks at 53 hours, *i.e.*, 2,650 hours. This equals 2·41d. per hour. For 7·25 hours =	£0	1	5·47
Power, five units per hour at 1·125d =	0	3	4·78
	£1	19	0·18

The cost per lb. of useful metal is therefore 2·78d.

Taking cost on the above basis, the value of *shoes and tyres is approximately equal*, and it may be considered immaterial which suffers the greater wear. In works where, by the use of improved machinery, the cost of labour on tyres is very low, it is possible that tyres will be cheaper than shoes, while conversely, where attention has been paid to obtaining the greatest possible wear from brake shoes, and scrap cut to a minimum, they would stand at a lower cost per pound of useful metal than tyres. On the assumption that the cost of shoes and tyres per useful lb. of metal is approximately equal, the combined wear of the various shoes and tyres tested is set out in a table in the Paper.

One of the most striking features is the greater wear with "dry" runs, this being contrary to that obtaining on service cars, and may be accounted for by the test wheel being absolutely clean and free from any material which would prevent the tyre and shoe coming into perfect contact, such as exists on tyres when running on the track, the brake shoe and wheel consequently seize, and, according to their characteristics, one or both suffers increased wear. Although there is this peculiar variation between the "wet" and "dry" conditions of tests, yet an approximation is quite apparent between the two. Considering the impossibility of having "dry" runs on the road track with perfectly clean surfaces, the writer is of opinion that the "wet" test, with its slight yet uniform lubrication by water, offers reliable and uniform means of comparison, and is quite adequate for the purpose of ascertaining the relative values of different grades of shoes.

The tests also show that shoes of the same grade, but from different founders, do not have the same frictional coefficient, durability, or wearing effect upon the tyre. In investigating this difference one naturally considers first their respective hardness, especially in view of the statement of so high an authority as the Brakes committee of the Master Car Builders' Association of America, who state in their official report, 1907: "The frictional effect and wearing qualities of each particular shoe depend entirely upon the proportion and texture of hard and soft material in its make-up." Also the statement of Mr. J. H. Panton in his Paper previously mentioned: "No matter what make of brake shoe is considered, if the proportion of hard and soft metal remains the same, the wearing properties will be

* Average; the figures vary from £5 to £10.

Digitized by Google

equal with correspondingly equal wear and friction." To determine the effect of this property the shoes have been tested for hardness by means of a "shore scleroscope." Examination of this property of the shoes demonstrates conclusively that shoes of equal hardness are not necessarily equal in durability, frictional coefficient or effect on the tyre.

Hardness having failed as a criterion of the durability of brake shoes, chemical analysis of the tested shoes, which had given extremes under test of durability and wearing effect on the tyre, was made. Definite conclusions, however, cannot be drawn from chemical analysis only, as it is well known that metals which have the same chemical contents do not necessarily have the same properties.

—	Silicon. per cent.	Sulphur. per cent.	Phosphorus. per cent.	Manganese per cent.
Shoe with minimum wear.....	1·23	0·31	0·67	0·52
Shoe wearing tyre least.....	0·79	0·24	0·02	0·54
Shoe with maximum wear.....	1·92	0·18	0·77	0·74
Shoe wearing tyre most.....	0·18	0·45	0·45	0·15
Shoe giving minimum combined wear	0·67	0·14	0·34	0·65
Shoe giving most combined wear	1·92	0·18	0·77	0·74
Shoe taken as standard for service tests	1·33	0·33	0·63	0·49
	1·14	0·06	0·65	1·73

The author is of opinion that if, in addition to chemical analysis and physical tests, a microscopical research was made of the structure of shoes which have been submitted to service and laboratory tests, the combinations of their constituent parts would be revealed, which would indicate the particular structures producing the different characteristics of the shoes, and probably enable a standard specification to be drawn covering the essentials required for the most economical and efficient grade of brake shoes.

Conclusions.—The conclusions arrived at by the author from the investigations described in this Paper may be briefly summarised as follows:—

The durability and efficiency of a cast-iron brake shoe is (1) a question of chemical composition, (2) the combination of its constituents and methods of founding.

From the cost point of view it matters little which suffers most wear—shoe or tyre. If financial economy is the only consideration, the shoe that gives the least combined wear, per unit of cost, will be the one to adopt.

When it is desirable to economise energy for brake application and to reduce mechanical stresses on brake gear to a minimum, it is obviously best to use a shoe with a high coefficient of friction.

Given correct designs of brake gear with ample stress margin and suitable method of power application, or its equivalent, financial economy can be made consistent with operative needs.

The Paper contains photographs of the apparatus employed, shoe fractures, and the surface of tyres in ordinary service.

DISCUSSION.

Mr. J. M. M'Elroy (Manchester) opened the discussion and drew attention to the principles underlying the matter of car braking. One of the limiting factors in the retardation of a car was the adhesion between wheel and rail; also there was the question of the best method of applying the brakes. He regarded the economic aspect of the problem as subservient to the more important item of efficiency. He wanted to advocate strongly standard specifications for brakes, tyres and rails. Then a uniform basis on which to build up some valuable data would be provided. He wished to include in his remarks some correspondence* which had passed between Mr. Mozley (Burnley) and himself. He also asked for information as to the rise of temperature between block and wheel. He thought that the question of brakes and wheels should be considered quite independently of the Corrugation Committee.

Mr. A. L. C. Fell (L.C.C.) asked for figures which could be used as a standard. He thought that the cost of removing wheels and axles should have been included in the author's figures. The cost of replacing a tyre was higher than that of renewing blocks; the latter could be done at night in the sheds and the car was not put out of commission. He thought that the effects of wear could have been as well obtained by weighing rather than by measurement. Again, tests in actual service were more valuable than laboratory tests. Chilled blocks should, in his opinion, be chilled right through; otherwise a surface chill would wear down in time and the block have to be renewed. As to the varying effects of wear, he asked for information as to the difference in wear of brake blocks over roads paved with wood and granite respectively. With the latter the grit from the setts tended to increase wear.

Mr. H. E. Yerbury (Sheffield) questioned the value of the micro-study of the metal in tyres and brake blocks, mainly on the ground that the factors entering into the problem varied so enormously. The human element also played an important part in the process of chilling. He asked for details as to the best depth of chill to adopt.

Mr. H. Mozley (Burnley) said that in some experiments made with hard brake blocks there had been an undue wear of the tyres.

Mr. G. R. Blackburn (Manchester) thought that wet tests were not altogether reliable, and further, he considered that the microstructure of the metals employed in blocks and tyres could be studied with advantage.

Mr. Dawson (in reply) said there were great difficulties in arriving at a standard shoe. In the matter of brake operation he thought that the leverage was not sufficient. In Bradford the leverage had been increased by 2 to 1 with relief to the drivers. There was no falling off of the coefficient of friction with rise of temperature. Wheels were only removed for re-turning, and in Bradford this was done every two years and in another two years re-tyring was done. He thought that the chief advantage of the microstudies of steel and iron was that the hand of the founder could be forced and he would take greater care in his deliveries. He recommended tramway men to find out what shoe gave them the best results, and when they had found it they should stick to it.

* In this Mr. Mozley calculated the various leverages required to produce the brake block pressures for the various coefficients of adhesion.

REPORT ON LUBRICATION OF CAR BEARINGS.*

A list of questions was compiled and issued by the sub-committee for the purpose of obtaining as much information as possible on the subject of lubrication of car bearings, the object of the sub-committee in compiling these questions being the eliciting of as full information as possible on the following points, viz.:—Class of lubricant used in every case and how applied, first cost and life of medium for conveying lubricant to bearings, cost of lubricant, intervals of inspection and cost thereof, horse power of motors, description of bearings and of what composed, amount of wear in bearings, cost of renewals of bearings, and particulars of cost and life of pinions and gear wheels.

Class of Lubricant.—It is interesting to note that the use of oil appears to be finding more favour, for out of a list of 56 tramway undertakings there are 16 towns using oil throughout, while 33 towns are using oil partially, and only seven towns are adhering solely to grease.

Application.—The method most favoured for application where oil is used is the usual spring pad for the lubrication of armature and suspension bearings. In other cases syphons are used, and in several instances steel and wool waste, moelline, elastic packing and splash system find favour relatively in the order in which they are placed. With regard to axle bearings, pads are used to a very great extent, while Armstrong oilers figure largely, and in some cases wool, hair, and steel and wool packing is used.

Cost of Lubricant.—The price per gallon paid for oil varies from 5½d. to 2s. There are quite a number of undertakings who use oil at a price varying from 8d. to 9d. per gallon, and there is also a fair number who pay 1s., 1s. 2d. to 1s. 6d. and 1s. 9d. per gallon. The highest price paid for grease appears to be 18s. 6d. per cwt., but the usual price appears to be about 12s. 6d. per cwt.

Inspection and Replenishing.—There seems to be a considerable advantage in the use of oil so far as the amount of labour required for inspection and replenishing is concerned. Where grease only is used, the necessary period of inspection appears to vary from once each 24 hours to twice per week. Where oil is used the intervals between examination vary from twice a week to once a week, every four weeks, and in one instance six weeks.

Cost of Inspection and Replenishing.—The replies vary greatly, the lowest cost experienced being 2·29d. per thousand miles, and the highest 2s. 10d.

Bearings.—White metal lined bearings find most favour, but there seems to be a considerable variety in the character of the alloys; only seven undertakings use solid bronze bearings unlined.

Wear.—The information given under this head is considered to be of the utmost importance, and it is interesting to note the number of miles which can be got out of bearings in different towns. As an instance, the following short table of half-a-dozen experiences helps to show the remarkably diverse character of the results obtained:—

A.	Miles per ½ in. wear,	armature,	5,300,	suspension,	—
B.	,,	,,	,,	5,000,	,,	6,000
C.	,,	,,	,,	3,000,	,,	—
D.	,,	,,	,,	51,000,	,,	16,670
E.	,,	,,	,,	38,500,	,,	45,000
F.	,,	,,	,,	38,000,	,,	114,000

* Abstract of the report of a sub-committee presented last week at the Conference of the Municipal Tramways Association. The sub-committee consists of Messrs. E. Cross (Rotherham), R. L. Acland (Chesterfield), P. J. Pringle (Burton-on-Trent) and T. R. Smith (Leicester).

Digitized by Google

The life for armature bearings varies from 84,000 to 5,000 miles but the average life appears to be between 10,000 and 12,000 miles.

Gear Lubricant.—There are eight towns who are using oil for the purpose of lubricating gears; the remainder use grease at about from 14s. to 16s. per cwt.

Life of Gear Wheels.—The life of gear wheels varies considerably in different towns, although the conditions are similar, and the class of gear wheels used are identical, with few exceptions. The highest mileage obtained is 10 to 11 million miles, although there is a reply which states, "None worn out yet." Another answer states, "None worn out after 5½ years use," the lowest mileage obtained being 52,506. Lives of 250,000, 200,000 and 160,000 seem to be fairly common, but many undertakings have had to be satisfied with mileages well under 100,000.

Life of Pinion Wheels.—Here again there is a great difference in the results, and it is interesting to note that in one case mileages of 2½ to 2½ millions have been obtained, and in another case from 150,000 to 200,000 miles. The lowest mileage obtained is 5,000, but there are instances where a mileage of 165,000 to 155,000 has been experienced. The bulk have had to be satisfied with from 70,000 to 40,000, while there are many well under the lower figure. It is interesting to find that specially hardened pinions have not found a place in the higher mileages, the best result attained being 112,000 miles, but this figure stands quite by itself, other results being much lower.

General.—The sub-committee have been struck with the remarkably short life of bearings in connection with traction work, and even the best instances recorded are short compared with those of stationary motors working under equally disadvantageous conditions with respect to heavy intermittent working. In comparing these types against each other there is one adverse circumstance under which the traction motor has to run, as compared with the stationary motor, and it seems that it is in this respect that the comparatively short life of the traction motor bearing is brought about. Take, for example, a motor driving a heavy crane in an engineering shop where the atmosphere is fairly loaded with dirt, and still under these circumstances bearings have been known to last for a great many years. In the case of the traction motor, when the car is running, there is a large amount of grit and dirt of the hardest kind, made up largely of fine particles of granite dust surrounding the motors, and unlike the engineer's shop, these particles are not floating about and allowed to fall by their own gravity, but they are driven by a pressure varying as the speed of the car into any interstices that may present themselves. Consequently, as the present oil or grease chamber is by no means rendered airtight, the grit finds its way into the oil or grease as the case may be.

The sub-committee are of opinion that a system of ring lubrication or its equivalent should be insisted upon in all new motors, and their tangible reason for this recommendation is the already excellent experience of those few undertakings who already have had these motors installed for sufficient time to give a decided opinion. Moreover, the evident advantages of such a system is shown by the fact that as the oil ring is to be relied upon to feed with an ample and generous supply, it does not become necessary to inspect or replenish so frequently, and an allowance of six weeks between inspections is not considered to be too daring. With the "ring" system the wasteage of oil is practically nil, and consequently a higher grade of oil can be used without affecting the cost materially, therefore, with the reduced number of inspections—which, by the way, would be carried on in the daylight under proper supervision—it would then be well worth while properly to joint all inspection doors in such a manner as to seal hermetically the oil well and bearing.

Given conditions similar to the foregoing, the sub-committee are of opinion that even the best results now obtained should be far surpassed in the future, and should bring the cost per running car-mile down in an agreeable manner by favourably affecting a number of items under that head. It may be of interest to know that two members of the sub-committee (Messrs. Cross and Pringle) had been previously experimenting, quite independently and unknown to each other, with a system of chain lubrication adapted to the older type of DK motor, so as to improve the lubrication of these motor bearings and to obtain the advantages of the "ring" system as far as possible under the conditions. Mr. Acland is also carrying out experiments with his Westinghouse (46 M type) motors in a similar direction. Some degree of success has already been attained, and the sub-committee have reason to believe that the experiments will end satisfactorily.

Replies to the queries have been of a most diverse character, and it would seem that some form of standardisation would be an advantage in the methods adopted in connection with lubrication of car bearings. Take, for instance, the cost of lubricant, the L.C.C. pay 5½d. per gallon for oil, while Glasgow pay 2s., The sub-committee lay particular stress on the inadvisability of using grease, or a combination of grease and oil, the latter being particularly objectionable on account of the liability of the grease to mix with the oil and so render the pads or other conveying medium inoperative.

There is a divergence of opinion as to the most suitable metal to be used for lining bearings, and consequently there is a great difference in the cost per thousand miles in the results under practically similar running conditions. It will prove to be most valuable information for all members to know the reason why Bury can obtain from 10 to 11 million miles out of their gear wheels, and how Glasgow and Keighley have been able to run their cars without renewals of gear wheels from the commencement.

It appears to the sub-committee that if co-operation between all undertakings was established with regard to the subject of this report, it might be that an undertaking, although having an excellent experience on the one hand, but unfortunate in other respects, would receive benefit by an interchange of ideas, and thus hope to arrive at the good results obtained by undertakings in other directions.

DISCUSSION.

Mr. C. W. Hill (Bournemouth) opened the discussion and said that a saving of £300 per annum had been effected at Bournemouth by paying attention to the oil used. They were largely in the hands of the oil makers, but he could not understand why Glasgow should pay 2s. and London 5½d. for their oil; he did not approve of cheap oils. The best oil for the purpose should be discovered and then adhered to. Dust was, he thought, the controlling factor in wear of car bearings. A dust-proof motor was badly wanted. At present oil boxes were little better than refuse bins. In seaside places the sand which penetrated to the bearings naturally occasioned excessive wear. He had not found that case-hardened pinions gave good results.

After some other members had taken part in the discussion Mr. Cross briefly replied to the effect that the matter would be further investigated.

TRAMWAYS IN RELATION TO TOWN PLANNING.*

BY A. BAKER.
(General Manager, Birmingham Corporation Tramways.)

After discussing some of the principal features of the Housing and Town Planning Act, 1909, the author lays down the dictum that "Means of communication is the first essential to successful town planning." Under the Act it is possible to restrict the number of houses to 12, or even less, to the acre. This means that the population must be spread over a greater area, and consequently further away from their work. It is obvious that it is cheaper to transport a number of persons congregated at a given point than to collect the same number of persons from several different points spread over a large area. It therefore seems that town planning will tend to make operating costs heavier.

It is certain that the cost of tramway operation cannot generally be reduced. There may be individual towns where little economies may be effected, but these would not materially affect the matter. How, then, can the situation be met? I think a lesson may here be learned from the Continent. In connection with town planning on the Continent, special provision in many of the new wide thoroughfares has been made for tramways. In some cases avenues in the centre of the streets have been specially constructed for tramway lines, other vehicular traffic not being able to use this part of the thoroughfare. In other cases the carriageway is divided into two portions, each of considerable width, by an avenue of trees. Where this has been done the tramway tracks have been laid close to the footpath on either side of the avenue, leaving ample room for other vehicular traffic. By these means a much higher average tramway speed can be attained. Again, where new thoroughfares have been made in sparsely populated districts and traffic is light, a cheaper method of tramway construction has been adopted. This is particularly noticeable in Berlin. In this city macadam paving has been largely employed, and as the ordinary wheeled traffic does not pass over it, it appears to be quite satisfactory as a tramway paving. In other cases no paving of any kind except at crossings has been used, but the rails are laid on sleepers and the space between the rails filled in with green turf. This not only cheapens the cost of construction and maintenance very considerably, but the effect of well-kept grass in the tramway areas is most pleasing.

The advantage to tramway traffic and to the ordinary vehicular traffic by having a portion of the road set apart exclusively for tramways is enormous. Besides obtaining a better average speed

* Abstract of a Paper read before the Municipal Tramways Association.

Digitized by Google
LIBRARY OF THE UNIVERSITY OF CALIFORNIA

collisions with other vehicles are obviated, and general repairs to permanent way, by its only being used for tramway purposes, considerably reduced. The width required for a double line of standard gauge tramway is 17 ft. If the carriageways of all the new main thoroughfares were made 91 ft. in width minimum there would be plenty of room for a special tram "way." A thoroughfare of these dimensions would provide for two footpaths each 10 ft. wide, two roads for vehicles each 24 ft. wide, and a way for trams 23 ft. wide. This 23 ft. would give two footpaths each 3 ft. wide for passengers leaving the cars, thus permitting them to alight in safety, instead of having to step straight on to the carriage way. If at the same time trees were planted on each side of the tramway, thus forming a tramway avenue, much of the objection to trams in suburban districts would be overcome, and a charming effect produced.

As to cost, we all know that paving forms a very considerable portion of tramway construction. The paving of one mile of double track costs approximately £3,000. By adopting this method of construction, which is really only possible in new districts, and through the agency of town planning, a very large saving can be made in the capital expenditure on tramways. There is no doubt that in many cases the landowners would be willing to give up the extra width required to make the wide thoroughfare here described, knowing that they would be benefited enormously by having such a main road adjoining their property. But, even where this could not be arranged, the price of agricultural land even near a large town could not be more than £100 to £200 per acre. Presuming the tramway authority was called upon to add 6 yds. to the width of the road, this would only mean an additional cost of not more than £400 per mile. In such a case a reduction of capital expenditure of upwards of £3,500 per mile of double track could be immediately made, allowing for extra strip of land, besides the very considerable saving that would be effected annually in repairs and maintenance. Such a cheap form of construction would enable tramway extensions to be made into districts of light traffic, which under present conditions cannot be contemplated.

In this connection I venture the opinion that such a cheap form of tramway construction is far more likely to assist town planning than any other form of traction, not even excepting the railless trolley system as we know it. Doubtless the latter system has a useful purpose to fill, in giving travelling facilities between sparsely populated districts where it would not be convenient to lay down tramways, or where they could not be constructed with any prospect of success; but there is no doubt that in districts which are capable of showing any signs of development it would be much better policy to lay down a tramway, and face a loss for a year or two, with the prospect of the tramway becoming remunerative at a later date. Trackless trolley cars can never deal with large masses of people like tramways, and in my opinion it would be the height of folly to instal such a system in a district which might in two or three years grow to such an extent as would render the system unequal to giving adequate facilities.

There is another lesson I think we may well learn from the Continent. In the new part of the old town of Ulm a great deal of land development is taking place. The municipality, after the old fortifications had become obsolete and partially removed, purchased large tracts of land which they have town planned. Certain portions of this land have been set apart for high class residences, other portions for middle class residences, and other portions again for workmen's dwellings. One district has been set aside for industrial purposes. Here factories, mills, warehouses, &c., are allowed to be erected. In selecting the industrial quarter regard has been had to the facilities afforded by railways and canals, and also as to the prevailing winds. The trams in Ulm also belong to the municipality, and communication has been provided between each district. Frequent services are run to enable workmen and others to get from one district to another. These tramways do not at present pay their way—indeed, there is a considerable annual loss on working. The municipality, however, is not at all concerned about this, because whatever the loss on the tramways amounts to is made up several times over by the profit on the sale of the land, and in the advantages accruing by having the town laid out on well-defined principles, to say nothing of the benefit accruing to the town by reason of the low death rate which inevitably follows the making of open spaces instead of congested areas. In Vienna, Frankfort-on-Main, and the great industrial city of Mannheim, the same policy obtains, although perhaps not to such a great extent as in Ulm, viz., that wherever new developments in land are taking place communication by tramways must be established, even though there is not much prospect of profit immediately accruing from the tramways.

In these towns it seems to be the settled principle that means of communication must precede population. This is certainly contrary to English practice. The first question asked when a new tramway has been proposed is, will it pay its way? Indeed, Parliament has hitherto been careful to inquire into the financial possibilities of all tramway proposals, and not a few have been rejected because the promoters have failed to satisfy Parliament that the proposed lines would yield an immediate return on the capital invested. This being so, the very important question is raised as to whether, in view of the new Town Planning Act, Parliament might not modify its view that tramways should not be constructed unless they can be shown to have an immediate prospect of yielding a profit.

I think it is of the utmost importance that tramway committees and their officers should keep in close touch with those charged with the conduct of housing and town planning affairs. This is recognised in Birmingham, where a town plan is in course of preparation. This provides for arterial roads varying from 80 ft. to 120 ft. in width.

DISCUSSION.

Ald. E. PRIESTLEY, in opening the discussion, said that what Mr. Baker had foreshadowed would take 100 years to accomplish. His figures were ideal on paper, but experience proved that the value of land was always put up by property owners when it was known that the municipal authority wanted to purchase for road construction.

Councillor BARROW (Birmingham) said they were not waiting 100 years in Birmingham, but would soon have a scheme, on the lines outlined in the Paper, in actual operation. The four main townships outside Birmingham had grown in population from 88,000 in 1891 to 230,000 in 1908 and that was a striking proof of the value of tramway operation. He commended the managers to study the Town Planning Act.

Mr. C. W. HILL (Bournemouth) thought that in Mr. Baker's ideal tramway the cars should run up and down the sides of the main road and not in the centre. This up and down traffic would facilitate the entry and exit of passengers. He also advocated circular routes. For one thing if a passenger was careful and sat still he could make two circuits for the price of one. In Bournemouth they had found the landowners willing to co-operate in their town planning scheme.

Mr. P. FISHER (Dundee) did not approve of the running of the tramways at a loss in the initial stages. If the traffic would not perimt the laying of a track at first then the trackless trolley should be used to develop the new districts, and when the heavier traffic came along then rails could be laid and the same overhead equipment used.

Mr. J. B. HAMILTON (Leeds) said that Mr. Baker's ideas suggested speculation in land outside the boroughs, but this was too uncertain a matter to be discussed further at the moment. He approved of the trackless trolley for development purposes, but pointed out that on many of these suburban routes where private right of way could be got, the construction of the track made the tramway a good competitor of the trackless trolley. The cost of the land was recouped largely by the cheapening of the track construction.

Mr. BAKER (in reply) said that it was a fact that good agricultural land could be bought in the 5 miles radius of Birmingham for £100 to £200 an acre. The trackless trolley he thought to be both complicated and expensive, and when tramway extensions were wanted the whole equipment would have to be scrapped.

THE EFFICIENCY OF SHORT-SPARK METHODS OF GENERATING ELECTRICAL OSCILLATIONS.

BY W. H. ECCLES D.SC., AND A. J. MAKOWER, M.A.

In a recent Paper read before the Institution of Electrical Engineers we published some measurements of the efficiency of transference of oscillatory energy from the circuit containing the discharge gap to a circuit representing the aerial wires in a plant for wireless telegraphy. The method employed consisted in measuring calorimetrically the energy supplied to the discharge gap, the energy wasted there as heat, and the energy passed into the aerial circuit; the method is direct and involves no assumptions. Our principal result was that the efficiency reckoned from the terminals of the discharge gap was, in the best disposition of our apparatus, rather less than 50 per cent. This figure is much lower than that claimed by makers of wireless telegraph apparatus of the type discussed. The Telefunken Gesellschaft claim to reach in normal plant 75 per cent. efficiency, and the Lepel Wireless Synd. claim to get higher than 60 per cent. Our apparatus was not precisely the same as that of either of these firms, but was rather of an intermediate nature. Nevertheless, it was our opinion that the discrepancies stated above were due to differences in methods of measurement, and we welcomed an offer to witness experiments in the Telefunken laboratory. Their method of measurement is indirect, and rests upon one that is widely applied in the determination of the logarithmic decrements of vibratory circuits. In order to estimate efficiency,

Digitized by Google

the supply of power to the discharge gap is directly measured by a wattmeter and the current in the circuit representing the aerial is read on a hot-wire ammeter; thus the power developed in the aerial circuit becomes known as soon as the high-frequency resistance of that circuit is determined. This resistance is determined by aid of a damping-factor method, which is as follows: A resonant circuit comprising an inductance, a variable condenser and a low-resistance thermal ammeter is loosely coupled to the aerial circuit under test, and adjusted to resonance—a state indicated by a maximum reading of the thermal instrument. It is now mistuned by variation of the condenser so that the power given to the instrument is halved; there are two values of the capacity that will effect this, one greater and one smaller than the capacity C_r that gives resonance. Call these C_1 and C_2. The approximate formula deduced by Bjerknes for the current induced in a resonator gives for the method described the formula

$$\delta_1 + \delta_2 = \frac{\pi}{2} \cdot \frac{C_1 - C_2}{C_r}, \quad \ldots\ldots (1)$$

where δ_1 is the logarithmic decrement of the aerial circuit and δ_2 that of the resonator, both decrements being reckoned per whole period, T, of the aerial oscillation. The decrement of the resonator can be calculated from the formula $\delta_2 = \frac{R_2 T}{2L_2}$, where R_2 and L_2 are the resistance and inductance of the resonator, and are known. Thus the decrement of the aerial circuit is given by

$$\delta_1 = \frac{\pi}{2} \cdot \frac{C_1 - C_2}{C_r} - \frac{R_2 T}{2L_2}. \quad \ldots\ldots (2)$$

The resistance of this circuit is given by $R_1 = \frac{2L_1\delta_1}{T}$, and the power consumption therein is C^2R_1, where C is the current recorded by the hot-wire ammeter in the circuit.

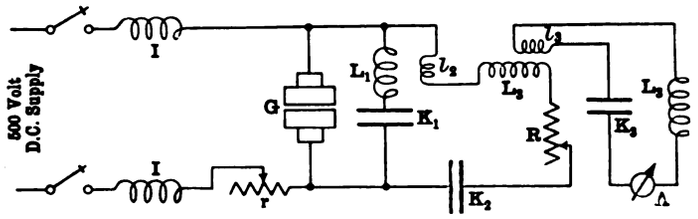


FIG. 1.

The method is, obviously, open to the criticism that it is based on a theory of the resonator which is admittedly not accurate for such great variations of capacity as are made in the use of the method. The limitations of the Bjerknes formula are well known, and have, in fact, been discussed mathematically; and the discussion might be carried forward into an examination of the theoretical limitations of the above method, and the deduction of formulæ of correction. We decided, however, to test the method by experiment rather than by theory. Accordingly, the method was applied to measure the effective resistance of an aerial circuit into which different known resistances were introduced in turn. In addition, each resistance was measured with four different resonators of widely differing electrical dimensions. Throughout the measurements the circumstances of the short-spark circuit in which the oscillations were generated were, of course, kept unchanged.

The diagram of the circuits employed by us is given in Fig. 1. The gap G, which is formed by two copper plates, water cooled and separated by a ring of paper, is connected to a 500-volt continuous-current supply through a regulating resistance, *r*, and choking coils I. The gap G, the large capacity K_1 and the small inductance L_1 form the oscillation generating circuit. The aerial conductor is represented by the capacity K_2, the inductance coils l_2 and L_2, and the resistance R. The resonator used in the experiments consists of a variable capacity, K_3, the inductances l_3 and L_3, and a sensitive short-period thermal instrument A.

The electrical dimensions of the apparatus were as follows: $K_1 = 300{,}000$ cm.; $K_2 = 1{,}680$ cm.; L_1, L_2 and l_2 were chosen so as to keep the period of the oscillations $4{\cdot}66 \times 10^{-6}$ seconds (wave-length 1,400 metres) in each branch throughout all the changes of the resistance R. This resistance was a frame of fine copper wires, and took values varying from 5 to 120 ohms in the course of the experiments. In the resonator, K_3 varied from 340 cm. to 5,200 cm., L_3 from about 1,430,000 cm. to 72,000 cm., and l_3, which was a movable "search coil," had the fixed inductance of 22,600 cm.

Experiments were made on eight different values of the resistance R. At each of these values, after the necessary retuning of the aerial branch by aid of L_2, the method described above was applied to determine the resistance. When R was large the coupling between the resonator and the aerial had to be larger than when R was small, but the coefficient of coupling never exceeded 0·05. Each determination of resistance by the method under criticism was carried out with four very differently dimensioned resonators in turn. A comparison of these indirect determinations with the known values of the various resistances is given below.

Table I. gives details leading to the calculation of the decrements of the resonator in its four different dispositions, (*a*), (*b*), (*c*), (*d*), which are needed as corrections in the next table.

Table I.—*Decrement of Resonator.*

	Capacity, K_3 cm.	Inductance, $(L_3 + l_3)$ cm.	Resistance,* R_3 ohms.	$\delta_2 = \frac{R_3 T}{2(L_3 + l_3)}$
(*a*)	340	$14{\cdot}53 \times 10^5$	5·7	$9{\cdot}1 \times 10^{-3}$
(*b*)	540	9·08	5·1	13·1
(*c*)	1,150	4·50	4·6	23·8
(*d*)	5,200	0·95	4·1	101·0

Table II. is practically the record of the measurements, and gives the sum of the decrements of aerial and resonator, as calculated from the half-power formula (1) above, for each of the four dispositions of the resonator.

Table II.

$\delta_1 + \delta_2$ from $\frac{\pi}{2} \times \frac{C_1 - C_2}{C_r}$.

Actual resistance, R.	(*a*)	(*b*)	(*c*)	(*d*)
4·7	0·116	0·105	0·180	0·306
7·1	0·102	0·152	0·181	0·310
12·7	0·149	0·222	0·220	0·410
21·3	0·269	0·245	0·310	0·400
35·0	0·359	0·326	0·335	0·503
55·0	0·468	0·432	0·503	0·575
87·0	0·620	0·557	0·540	0·640
123·0	0·663	0·712	0·702	0·810

These two tables lead to Table III., wherein appear the calculated effective resistances of the aerial circuit.

Table III.—*Calculated Values of Resistance R.*

Actual resistance, R.	(*a*)	(*b*)	(*c*)	(*d*)
4·7	13·5	11·6	19·6	26·1
7·1	11·8	17·6	19·9	26·6
12·7	17·7	26·4	24·8	39·1
21·3	32·8	29·3	36·1	37·9
35·0	44·1	39·4	39·2	50·8
55·0	57·4	52·4	59·9	59·4
87·0	76·0	67·7	64·2	67·2
123·0	80·7	86·2	83·7	87·6

Finally, Table IV. gives the ratio of the calculated resistances in Table III. to the actual resistances.

Table IV.—*Ratio of Calculated to Actual Resistance.*

Actual resistance, R.	(*a*)	(*b*)	(*c*)	(*d*)
4·7	2·87	2·47	4·17	6·05
7·1	1·66	2·48	2·81	3·75

The results of the experiments may be looked at in two principal ways. In the first place, if the numbers in a column of Table IV. be plotted with actual resistances as abscissæ, we can examine the half-power method as employed with a resonator of fixed electrical dimensions. For example, in Fig. 2 the numbers obtained with resonator (*d*) are plotted. If the method were trustworthy a horizontal straight line (shown dotted) would be obtained. Instead, a falling curve appears which displays great departures from the truth in the low resistances. In the second place, we may inquire into the working of the method when a certain aerial resistance is

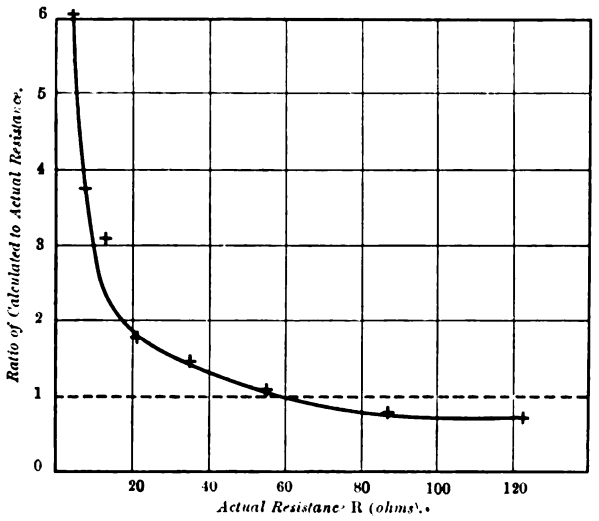

FIG. 2.—RESONATOR (*d*).

measured by means of different resonators in turn. This is done in Fig. 3. Each curve corresponds to a horizontal row of Table IV., the abscissæ being the inductances of the changing resonator. The departures from the correct horizontal straight line (shown dotted) are very great, especially when the aerial resistance is low. It appears that the estimated resistance of the oscillatory circuit may vary more than 100 per cent. when it is measured by different resonators, and the estimated resistance may be as much as six times the actual aerial resistance. The cause of the former kind of error lies probably in the fact that

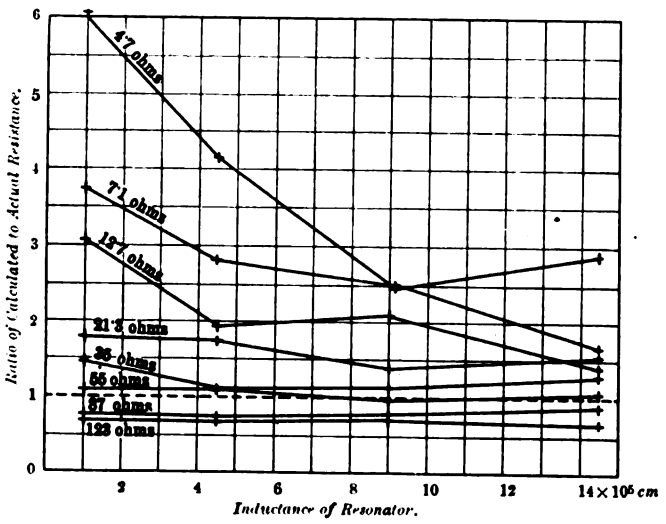

FIG. 3.

the formulæ of Bjerknes are not strictly applicable to the half-power method of measuring the decrement. The second kind of error probably arises in the discharge gap. It is to be expected that when the aerial resistance takes different values the physical conditions of the discharge may alter. The present experiments indicate that the proportional wastage in the gap increases as the aerial resistance decreases. In other words, the reaction of the aerial branch currents on the discharge is such as to add a fictitious part to the estimated resistance of the aerial branch.

It is plain, then, that if the efficiency of the whole plant is measured by this half-power method for decrement—the estimated resistance being multiplied by the square of the virtual amperes in the aerial branch in order to get the power delivered to the branch—a result is obtained which may be much too large when the resistance in the aerial branch is small. In the particular instance presented by our own apparatus, the efficiency would probably work out fairly correctly if the aerial resistance were about 60 ohms, but would be too large with smaller aerial resistances and too small with larger aerial resistances. In the extreme case shown in Fig. 2, since the estimated resistance has six times its actual value, the estimated efficiency would be six times too large.

ELECTRIC RAILWAY CATENARY TROLLEY CONSTRUCTION.*

BY W. N. SMITH.

(*Continued from page* 938.)

Summary.—The author describes recent practice in catenary construction, discussing the various features of the different forms in use. He believes that the roller type of trolley may possibly prove a distinct improvement over the present sliding bow for trunk line work.

Catenary Hangers.—For the plain type of construction there now seems to be a preference for a hanger that has an easy or flexible grip on the messenger wire and a powerful positive grip on the trolley wire, with a joint between clamp and rod, either at the top

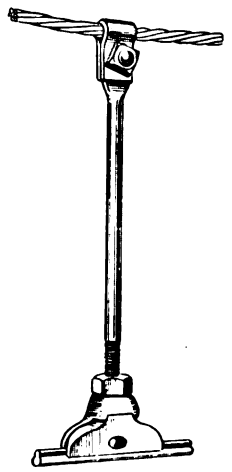

FIG. 5.

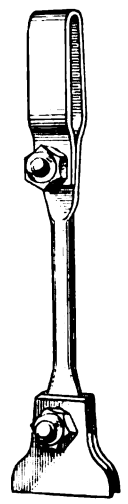

FIG. 6.

or bottom, or sometimes both, to increase the general flexibility. In the earlier work, four or five years ago, messenger and trolley clips were rigidly connected together and even in spite of the lack of experience in design and erection they operated very well in many cases, provided the trolley wire was pulled sufficiently tight. The Connecticut Co. recently constructed several miles of experimental catenary construction, and some of the designs of hangers† are reproduced in the present Paper.

It is safe to say that almost every engineer who has built a catenary line has tried his hand at devising a new catenary hanger that would combine simplicity, flexibility, certainty of grip, speed of application and adjustment, and cheapness. Fewness of parts is essential to cheapness and speed of adjustment. A hanger of five or six parts, including bolts and nuts, is preferable to one of 10 or 12 parts. The grip on the trolley wire should be powerful and easily applied. One nut only should be allowed, to tighten or loosen the trolley clamp. The hanger shown in Fig. 5 seems to answer most of these requirements. The writer's preference is for a nut screwing down on the lower end of the hanger rod as in Fig. 5, as it can then never work off. It is desirable to have at least one pivot joint in the rod, either at the messenger or at the trolley ear. The loop type of connection to the messenger wire where the top of the rod is practically looped over the messenger wire, or forms a slot for the entire hanger to work up and down on the wire as in Fig. 6, has only one

* Abstract of a Paper read before the American Institute of Electrical Engineers.

† A description of the experimental installation appeared in THE ELECTRICIAN of April 15th, 1910, p. 12.

Digitized by Google

drawback and that is the possibility of wearing away the galvanising of the steel messenger cable. If the messenger be of copper the wear would probably injure the cable mechanically. This type has also the advantage of permitting the endways movement of the contact wire which will allow its tension to be well equalised on different sections of the line.

There is one feature of catenary design that always deserves careful attention, and that is the number of different lengths of hanger rods in a span. The average railway will have more or less curvature, and spans of different lengths on the same, in which the number of inches sag of the messenger will vary considerably, though the old spacing interval of the hanger rods is ordinarily uniform no matter what the distance between poles or bridges. On the Erie R.R. electrification there was little curvature and the number of different lengths of span was limited, and only six different lengths of hanger rod were needed, with 10 ft. spacing. On the Denver & Interurban there was considerable curvature; the spans varied from 120 ft. down to 60 ft. in length, spacing 10 ft., and yet there were only six lengths of hanger rod required.

It is noticeable that there is a tendency toward increasing the distance between hanger points in catenary spans. It originally started at about 10 ft. One company, during the early development, advocated three-point suspension on tangents for spans as

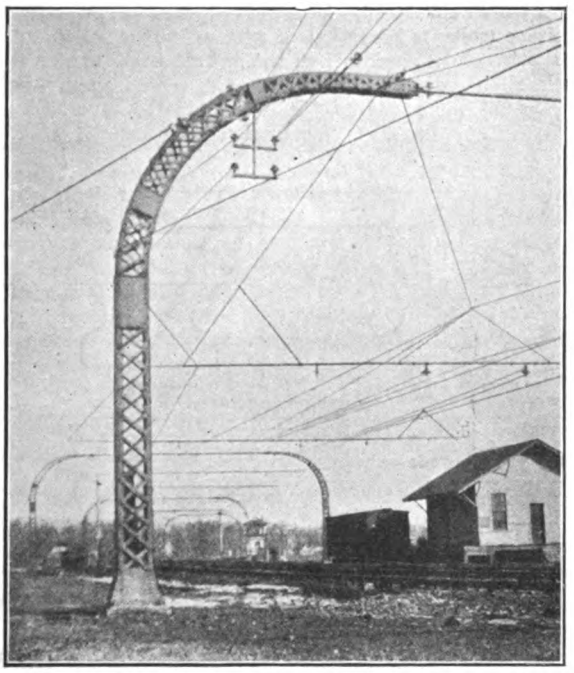

Fig. 7.—New Catenary Construction of New Haven Railroad.

long as 150 ft. At the present time, however, the three-point suspension is only recommended for wheel trolley operation and 11-point suspension is recommended for sliding bow operation. This brings the hangers approximately 14 ft. apart. Another company shows spans varying between 10 ft. and 13 ft. 7½ in., which is 12 points of suspension for 120 ft. span, and 11 points for 150 ft. span, as desired. A third company gives in its catalogue fittings designed for 10 ft. and 15 ft. spacing, on spans from 60 ft. to 150 ft.

The American Street & Interurban Ry. Association's Committee on Power Distribution prepared a report on catenary construction in 1908, and its conclusions were rather in favour of hanger spacing of 20 ft. to 30 ft. because the sag between hangers, though very slight, would still be sufficient to help take up the expansion of a copper trolley wire in warm weather. It was quite evident that the Committee hesitated to recommend the complication of the compound catenary type of construction if any means could be adopted that would accomplish reasonably smooth operation with plain catenary construction. It also reported very favourably on making spans 300 ft. in length; that the hangers should be as light and flexible as possible and that the messenger cable should be of steel, strung to a small sag.

Much is said from time to time about the necessity of staggering the trolley wire from side to side when constructing for sliding bow operation. The writer has noted enough successful operation without staggering to confirm his belief that it is not absolutely necessary under interurban conditions with average track and motor cars of the usual interurban type. With these conditions the car is generally so sure to sway from side to side as to equalise the wear fairly well on the sliding bow. It is only where there are very heavy locomotives and extremely solid track and roadbed that the writer would entertain seriously the necessity of staggering the wire; but though these conditions are present on the New Haven Road, the contact wires have not been staggered. Unless great pains are taken to prevent it a staggered wire always tends to pull straight and consequently to induce some sag that is not desired.

The new design of heavy catenary construction developed last year by the New Haven road is a remarkable advance in several respects, and is illustarted in Fig. 7. The chief points of interest are the following: (1) The supporting bents are much more sightly and more economical of material than the original bridges. (2) The main suspension cables of 1¼ in. stranded steel wire which carry the insulators and the messenger wires proper are uninsulated and earthed, which will facilitate maintenance, painting, &c., and will obviate much of the danger to men on the signal bridges. (3) Insulators, if broken, can be replaced by removing only three bolts, the two by which the insulator is suspended from the crossbent and the one which suspends the messenger wire from the insulator. (4) The feature of a steel working trolley wire below a copper conductor, using the elasticity of the upper wire to permit the contact wire to yield in an upward direction, is here repeated, showing it to be regarded as a successful means of securing smooth and reasonably flexible contact. (5) The necessity for steady strain insulators and pull-offs of the previously accepted types on curves is entirely done away with because the hanger rods are so dimensioned that by inclining them at such an angle that the trolley wire follows the alignment of the curve exactly, the tendency is for the lower wire to pull to a curve of shorter radius than the messenger wire. By adjusting the lengths of the hanger rods with some care the curve

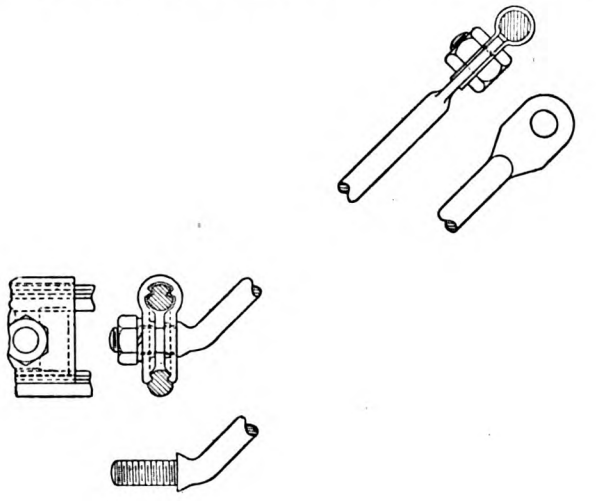

Fig. 8.—Bent Inclined Hanger Rods.

of the centre line of the track can be closely approximated by the lower ends of the hanger rods when thus inclined and rightly adjusted for length. By bending these inclined hanger rods so that their bottom ends are horizontal, then passing the horizontal end through the middle of the clip that fastens the contact wire to the secondary messenger, the two latter are held rigidly in a vertical position and the working trolley is maintained as exactly under the secondary messenger as though it were on a straight line. (*See* Fig. 8.) The criticism is sometimes made of steady-strain insulators for catenary curve construction that the tension under which they do their work makes the curve rigid and unyielding. In this case the heavy steady-strain insulators are dispensed with altogether, being replaced by the light iron hanger rods which for the time being are acting as steady-strain insulators. Their greater frequency must minimise the pull of each individual rod and tend to make the whole structure less rigid than where steady strain-insulators or pull-offs are applied at intervals of 30 ft. to 60 ft. (6) The adjustments for height in this construction are extremely simple, being accomplished by slipping the suspending members of the cross bents nearer to or further from each other along the bent, thus raising or lowering it.

Steady Strain Insulators.—Steady strain insulators usually consist of a stick of treated wood shaped like a long strain insulator, terminating at the outer end in a hook-shaped fitting that is attached to the trolley car, being pivoted at the inner end to an insulator on the bracket. When in this form they must be inclined upward away from the trolley wire so as to clear the sliding bow. While originally intended for curve construction only, it is often found

Digitized by Google

desirable to instal them at intervals along tangents, say, from 5 to 10 poles apart, as their presence helps to prevent swaying of a suspended trolley wire in a very high wind.

The form of steady strain insulator used on the Denver & Interurban Ry. is shown in Fig. 9. This has the merit of employing the same kind of 11,000-volt insulator that is used on the standard straight line catenary support, the head of which is cemented into a socket on the end of a malleable iron bar bolted to the bracket. The brace proper is a short link of malleable iron loosely hooked into an eye-bolt projecting from the bottom of the insulator. It will thus swing through an arc permitting some longitudinal movement of the trolley wire. In case the insulator breaks it will fall to the ground from the outer end of the hook, and the hook is light enough so that the stiffness of the trolley wire will make it stand out straight after the insulator has fallen and it will not hang down and foul the sliding bow.

Between poles, various schemes for pull-offs are used, but the commonest method is to run a bridle from the upper and lower ends of the hanger spacing rods, joining the bridle wires at some distance away from the trolley and insulating the pull-off by a strain insulator. Sometimes a wooden strain insulator may be put into each of the bridle wires, but care must be taken not to weight them down so that they would be in danger of fouling a bow trolley. Probably the best way to insulate a pull-off for high voltages is to use the disc type of strain insulator.

Strain Insulators.—The writer's experience with catenary construction having been with high voltages, it has been necessary to be particular about strain insulators. After some unfortunate experiences with strain insulators built up of metal and moulded insulating material of one form or another, it was found that porcelain, if it could be kept in carefully equalised compression, was the most reliable insulation, and as in the case of the straight-line insulators, a single insulator (of the heavy porcelain spool type), properly mounted, can always be depended upon. The easiest way to mount such insulators is to cement them upon a piece of pipe large enough to carry a $\frac{7}{8}$ in. or 1 in. bolt. If a bore of the spool is fairly large it

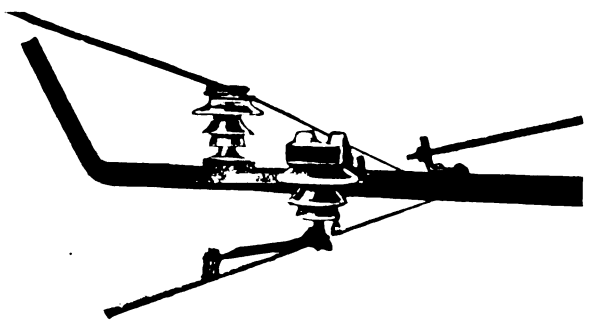

Fig. 9.—Steady Strain Insulator, Denver & Interurban Railway.

may be necessary to use $1\frac{1}{2}$ in. pipe. It is more necessary to have the pipe nearly as large as the insulator than it is to have the bolt nearly fit the pipe.

The disc type of insulator is very ingenious, light and attractive, but the body of the porcelain under compression is not sufficient to resist a crushing strain of more than 5,000 lb. or 6,000 lb., or it was not when certain tests were made under the writer's supervision between two and three years ago. The $6\frac{1}{2}$ in. diameter disc insulators are now advertised to carry a safe working load of 2,500 lb., and the 10 in. insulator 4,500 lb. With the trolley tension sometimes reaching 5,000 lb. at low temperature, a strain insulator for dead ending must have a working capacity of at least 7,500 lb. to 10,000 lb., and it ought to be as high as 12,000 lb. to 15,000 lb. This puts the disc type out of the running. The writer designed for the Denver & Interurban a double spool insulator comprising a porcelain spool cemented on $1\frac{1}{4}$ in. pipe with $1\frac{1}{2}$ in. by $\frac{1}{2}$ in. flat iron driven through the pipe and standing edgeways to the strain, there being a hole in each end of the flat iron for linking to the other porcelain similarly fitted. This insulator, under test, withstood 50,000 volts and 14,000 lb. mechanical stress simultaneously, without failure. It is shown in Fig. 10.

It is the writer's belief that, even more than in the case of direct suspension, strain insulators for catenary construction should be specified to be tested mechanically and electrically at the same time up to their maximum mechanical and electrical capacities. It is only in this way that actual conditions of service can be duplicated in a test. An excellent point about the disc type of insulator when used within its capacity is that there is a mechanical linkage of the guy cables on opposite sides of it which prevents their falling apart if the porcelain burns. This is not true of a wood strain insulator, which under high voltages is much more likely to get burned in two than at low tension, and for this reason the writer does not believe in using wood strain insulators for heavy strains where there is any possibility of a full voltage being applied to opposite ends of the insulator.

Deflectors and Frogs.—The deflector has sometimes been found necessary to prevent the horns of the pantograph bow trolley from getting tangled in the wrong wire where two trolley wires intersect on a switch or crossing. If the bow has no horns or if the horns are prolonged downwards there is no danger of a bow catching and no necessity for the deflector. In fact, deflectors are about the worst nuisance one has to contend with in maintaining a catenary line, and even where they have been carefully installed they are very apt to give trouble. It is very difficult to stretch the intermediate wires perfectly tight, and to keep them tight, even after they are adjusted.

Section Insulators.—With wheel trolleys, wood section insulators are a necessity, as in the case of direct suspension, but by far the best form of section insulator for bow trolley operation is the overlapping break without any wood or any other insulated under-run. They are also cheaper to instal than the wooden insulator, there is far less weight to support, and there is no danger of warping or of destruction by fire. Section insulators make good feeding-in points and should always be fitted with a jumper which includes a knife switch, usually kept closed. When it is desired to open a section of high-voltage trolley a hooked stick with an earthed chain attached above the handle is used to pull the switch, being kept hung permanently in the switch box, which should be well up on a pole out of reach of all but employés. It is desirable to have such switch boxes located at railroad stations or signal towers.

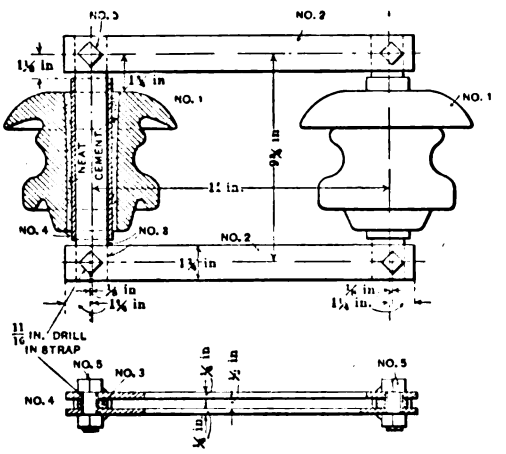

Fig. 10.—Double Spool Strain Insulator.

On two important installations of 11,000 volts, with multiple unit car operation, no feeder wire has been found necessary and section insulators have been introduced mainly for subdividing for the purpose of more readily locating trouble.

Lightning Protection.—It is absolutely necessary at high voltages to earth all the brackets and spans of a catenary line. This is most effectively done by steel or iron bars about $\frac{5}{16}$ in. or $\frac{3}{8}$ in. by $1\frac{1}{4}$ in., with the top end bolted to the butt end of the bracket and the bottom end run over to the track through the ground from the butt of the pole. The best kind of a connection to make with the track is through a cross bond, as this is more flexible than to connect a rod directly to one of the rails. The earthed rods, brackets and truss rods together form a pretty fair lightning protector for the trolley construction, but to make it more effective, on the Denver & Interurban Railway a $\frac{5}{16}$ in. steel earthed cable was run on the tops of all the poles and connected to every bracket, and at every fifth pole an earthed rod was run down the pole and attached to a cross bond and also to a pipe or a plate, the latter being used when there was any moist earth near at hand. This general scheme is the cheapest method of combining the earthing of brackets and lightning protection and it has an additional advantage of stiffening the pole line considerably. If circumstances make the use of line lightning arresters desirable, the swinging fuse type may be installed at intervals of $\frac{1}{2}$ mile. This arrester has given good service for three years on the Erie Railroad, at 11,000 volts.

Splices.—For a trolley wire at ordinary tension, the old forms of splicing sleeve did fairly well, but where the tension is great and the wire very stiff, as with phono-electric or steel wire, the old form of sleeve, with the necessity of curving the wire slightly in order to get it through, is inconvenient, especially for emergency work. A

Digitized by Google

sleeve with both holes bored perfectly straight and inclined slightly upwards towards the centre will allow the trolley to enter and pass through without binding. To ensure sufficient strength this type of sleeve is made out of rolled bronze about 1 in. square with rounded edges, as shown in Fig. 11. Experiments showed that it was not safe to depend upon a mechanical splice that involved bending trolley wire beyond the elastic limit, although such a splice would be very quick and easy to make. For splicing messenger wire, use is made of cable splicing sockets shown in Fig. 12. To prevent the messenger wire from pulling out, the ends of the strands were doubled back on themselves, the cable end pulled back hard into the socket, and babbit poured in.

Moving Contact.—It is the writer's impression that the high-voltage catenary construction now in use is in nearly all cases operating under conditions favourable to the sliding bow. The conditions on the New Haven road are doubtless more severe than any other, as they involve high speeds, many low bridges, and the heaviest currents yet demanded in alternating-current railway work. On nearly every other single-phase alternating-current railway the traffic is in single-car trains, or with much lighter locomotives, and at lower speeds. More skill and judgment are needed to erect and maintain catenary than direct suspension, and experience shows that the fundamental difficulties preventing smooth operation arise primarily from the expansion and contraction due to changes in temperature, which must be overcome by following some of the methods herein suggested.

Barring the tendency of the old-fashioned trolley wheel to jump at high speed, even on fairly well aligned wire, it has proved a reliable contact maker up to the limit of its capacity, and has shown itself readily adaptable to all conditions of sag in long spans. The gradually increasing use of the catenary construction with the wheel trolley, a combination which seems to be well thought of by railway operators, encourages the writer to believe that in the heavy railway work of the future on trunk lines or over long distances, where high-voltage alternating current is the obvious solution, the rolling contact will tend to reassert its superiority over the sliding bow. The manufacturing companies, to whom engineers generally look for progress in such directions, cannot be said to have made much progress in this direction during the last few years. Although the writer has not been in a position to conduct any experiments

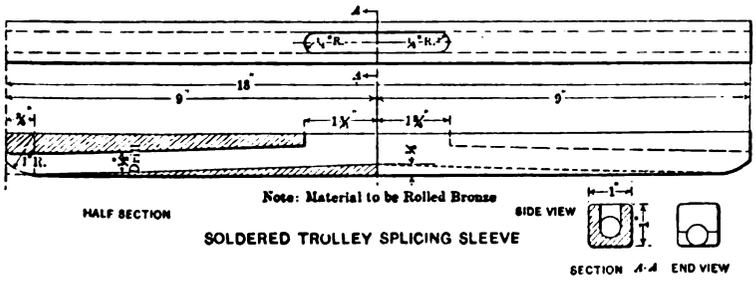

FIG. 11.

with the roller type of trolley, nevertheless, in the absence of convincing proof to the contrary, he is disposed to believe that it may yet be so developed as to constitute a distinct improvement over the present sliding bow, in the rough and ready service which the trunk line work of the future is likely to require.

As has been the case before in some practical electrical matters, progress in this respect has had its start on the Pacific Coast. On the interurban cars of the San Francisco, Oakland & San Jose Railroad there are now in use pantograph roller trolleys of the type shown in Fig. 13. The roller for these trolleys, which is held against the wire by a spring connected with the pantograph, is a brass cylinder 5 in. outside diameter and $\frac{1}{8}$ in. thick. The pantograph has a vertical movement suitable to accommodate the rise and fall of trolley wire 14 ft. to 22 ft. above rails. This type of trolley requires little attention, and the brass cylinders show an average life of about nine months on cars making 250 miles a day. These cars are working on 600-volt direct current and have four 125 H.P. motors, so that the roller trolley evidently carries quite a respectable current. It is to be hoped that the heavy alternating current locomotive work of the future as well as the multiple unit car operation can be made even more successful than now, and the wear and tear on trolleys and line construction diminished, if the development of the roller contact trolley can only be given the attention to which it seems entitled.

The life of 67,500 miles for pantograph roller trolleys, computed from the above quotation, seems incredible, and in the absence of detailed records may be somewhat discounted; but it is quite evident that the device is worthy of consideration. The life of pantograph shoes is variously reported as from 8,000 to 15,000 miles on single-car interurban lines, and very much lower than this on the New Haven road, where the conditions of high speed, heavy currents, more rigid trolley construction and low bridges, all combine to wear them out rapidly.

Double Trolley Construction.—The writer has paid no attention in this Paper to double trolley construction as distinct from standard types, because it is used so little in the United States, either in direct or alternating-current systems. Where used, it is generally erected with the same types of overhead material used in single trolley construction. Europeans have worked it out for three-phase alternating railway equipment with all the care and neatness that char-

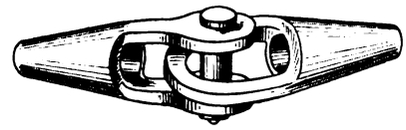

FIG. 12.—CABLE SPLICING SOCKET.

acterise their construction. They seem to be willing to put up with more complications in the accomplishment of results than does the average American engineer, and the principle of adherence to form rather than simplicity in attaining a result seems to prevail both in the personal side of railway administration and in the development of mechanical and electrical ideas. It is very doubtful whether any American railroad man will ever become reconciled to erecting two trolley wires of opposite polarity over any railroad track, if he can possibly get along with one. It is the writer's opinion that this one condition more than any other, will retard three-phase railway development in America.

In considering the development of heavy electric traction on

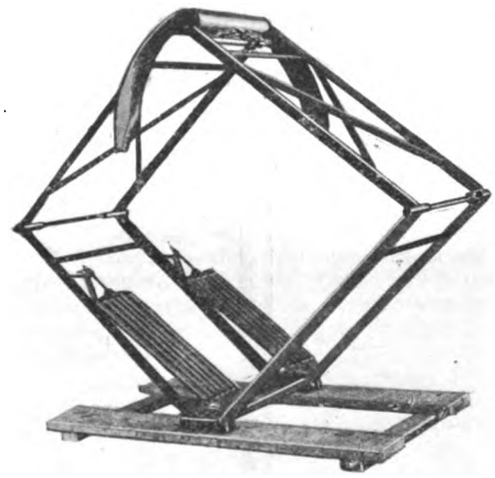

FIG. 13.—BROWN PANTOGRAPH ROLLER TROLLEY.

trunk line railways, therefore, we are brought back to our starting point by the controlling influence of the working conductor—namely, that it is the trolley system rather than the motor which is the characteristic feature of a railroad, and that that type or system of motors will ultimately prevail which can utilise the cheapest and most easily maintained working conductor.

[An account of the discussion on this paper will be given in our next issue.—ED. *E.*]

MAGNETIC BALANCE OF MM. P. CURIE AND C. CHENEVEAU.*

BY C. CHENEVEAU, WITH AN APPENDIX BY A. C. JOLLEY.

Summary.—The author first shows how the coefficient of specific magnetisation can be calculated from measurements with this balance, and then describes the apparatus. In an appendix particulars of tests on various materials carried out at the Northampton Institute are given.

This apparatus is intended for the measurement of the coefficient of specific magnetisation, of the susceptibility or permeability of feebly paramagnetic or diamagnetic bodies. The body whose magnetic properties are to be determined is suspended from one end of the arm of a torsion balance. By means of this balance the force

* Abstract of a Paper read before the Physical Society. A short account of the discussion in connection with this Paper appeared in THE ELECTRICIAN, May 20, 1910, p. 244.

Digitized by Google

is measured, which is experienced by the body when placed in a non-uniform magnetic field, produced by a permanent magnet whose lines of force cross the space occupied by the body.

The author first indicates the method of calculating this force. If I is the intensity of specific magnetisation and Hy the intensity of field, the value of the force is $f = mI\frac{\partial H_y}{\partial x}$, $\frac{\partial H_y}{\partial x}$ representing the space variation of the field. As we are only concerned with feebly magnetic bodies, the demagnetising force arising from the magnetisation of the body is negligible, and we may assume that the intensity of magnetisation is proportional to the field. If we denote

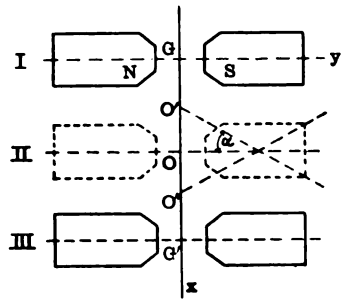

Fig. 1.

the constant ratio between the intensity and field, or coefficient of specific magnetisation, by K, we have $I = KH_y$, and therefore

$$f = KmH_y\frac{\partial H_y}{\partial x},$$

In bringing the magnet producing the field from a considerable distance the force, at first = 0, increases to a maximum at a certain point, O′ (Fig. 1), where the product of the field H_y, by its gradient $\partial H_y/\partial x$, is a maximum, and becomes zero again when the body O coincides with the centre of the magnet G (position II., Fig. 1). A minimum or negative maximum is reached by further rotation of

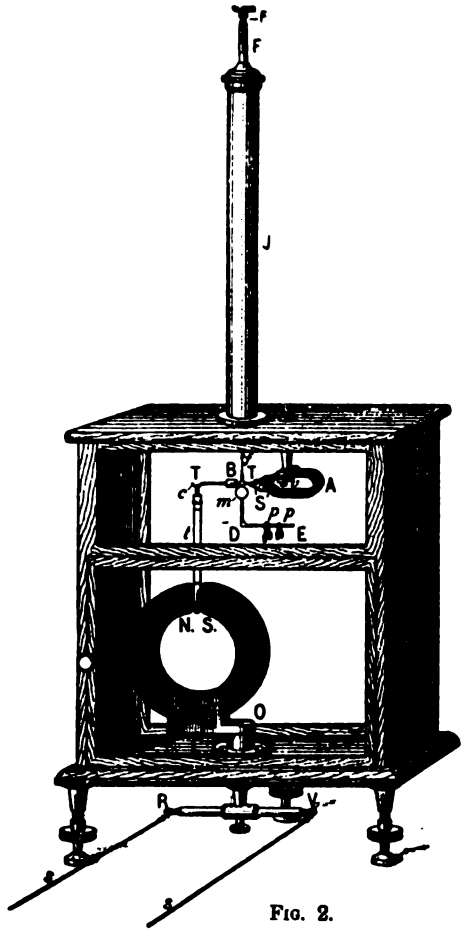

Fig. 2.

the magnet at a point, O″, symmetrical with O′, relatively to O, and becomes zero again after the magnet is withdrawn far from the body.

At every instant the action of the force is balanced by the torsion of the balance wire. If c is the moment of torsion per unit angle, and a the maximum deviation of the arm at O or O′ (Fig. 1), the equilibrium condition is $fl = ca$, l being the length of the balance arm. If the deviation is measured by lamp and scale, $a = D/2L$, D being the deflection of the spot upon the scale, and L the distance of the scale.

From the above equations

$$K = \frac{cD}{2mlLH_y\frac{\partial H_y}{\partial x}}.$$

This formula permits the absolute value of the coefficient K to be determined for a body if the other quantities are accurately determined. But the apparatus is especially adapted for relative measurements, and in this case it becomes extremely simple and practical, $Km/K'm'$ equalling D/D′, where m and m' are the respective masses. If the body is placed in a tube of glass or other substance, this tube being subjected like the body under test to the magnetic forces, an experiment must be made with the tube alone, and the effect due to the tube represented by a displacement of the spot D″ added or subtracted. This formula is not corrected for the effect due to the magnetisation of the air; the exact formula is obtained in the Paper.

If we take water as the standard body ($K' = -0{\cdot}79 \times 10^{-6}$), it enables us to obtain an absolute value of the coefficient of specific magnetisation of a body. It is convenient if the masses of the bodies compared correspond to the same volume; on this account the tube containing the substance is always filled to a given mark. When the substances tested are very strongly magnetic, a smaller length may be employed, but in that case it is absolutely necessary that the comparison substance should have the same length. The apparatus could be made still more sensitive with the aid of an electromagnet. On the other hand, with a torsion wire of larger diameter, the magnetic properties of iron or other ferro-magnetic metals and alloys could be determined. It would doubtless suffice to use an

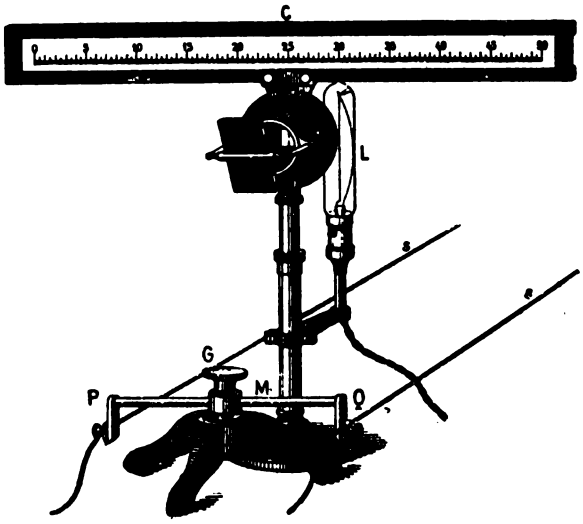

Fig. 3.

extremely fine wire of the metal, and to employ the method of experiment and the corrections already proposed by P. Curie in a work on the magnetic properties of bodies.*

Magnetically Damped Form of Instrument.—The arm of the torsion balance is formed by a rod, TT (Fig. 2), which carries from one of its two extremities a hook, c, from which the glass tube t, which contains the body, can be suspended. To this end the glass tube is closed by a cork carrying a metallic ring which hangs on the hook c. The tube t is therefore in a vertical position. On the other end of the arm TT is fixed a copper sector, S′, which moves between the poles of a fixed damping magnet, A. To vary the sensitiveness the torsion wire can be changed, and the damping varied by the position of the copper sector in the field. On the horizontal arm TT is fixed a vertical copper strip which carries a hook to which the torsion wire f ($\frac{1}{10}$ mm. platinum) is attached. Below, this strip is turned at right angles, as shown by the portion DE parallel to TT. Balance is obtained partly by the aid of a small copper cylinder, B, sliding on the rod TT, when the tube is empty, and partly by copper or aluminium riders, pp, to compensate for the weight of the solid or liquid material which fills the tube to the level marked.

The displacement of the magnet N.S. is obtained by a movement of rotation around an axis, O; this movement is smoother than the sliding motion of our earlier model. The movements of the torsion balance are followed by the observer upon a divided scale, C (Fig. 3). For this purpose a 2-metre radius concave mirror, m, is attached to the balance arm, and the image of a straight filament is employed. The displacement of the magnet is effected by a controller, M (Fig. 3), fixed in front of the scale, which consists of a horizontal rod, PQ

* Annales de Chimie et de Physique (1895).

Digitized by Google

turning about a vertical axis in a heavy base, and furnished with a large milled head, G, which can be turned by the observer. This rod is provided with two clamps, P and Q, which are attached by two cords to two rings, R and V, on a similar rod attached to the axis of the magnet NS. If the cords are initially arranged so that the rods PQ and RV are parallel, the position of the magnet is at once determined by the direction of the rod PQ, and it can be turned either by the milled head G, or preferably by holding the two cords *ss* like reins.

The advantage of employing a rectilinear filament lamp is considerable in practice, as the spot is always visible on the scale even if the torsion arm is not perfectly balanced horizontally.

Appendix.

One of these balances has been set up and tested in the laboratories of the Northampton Institute. The instrument was of the magnetically damped type described above, and was used with a lamp and scale at some 2 metres distant from the mirror. No attempt was made to obtain absolute values of the coefficients of specific magnetisation; but relative determinations only were made, using as a standard substance distilled water, and assuming for it the value $K' = -0{\cdot}79 \times 10^{-6}$, found by M. Curie.

The results obtained, some of which are given below, are set out in the accompanying table, and show some interesting figures.

Of the chemically pure liquids tested all exhibit diamagnetic qualities. The samples of aluminium are all magnetic, and we have not been able to get a sample which is less magnetic than the first of these. Eleven samples of brass showed a great range of magnetic qualities. Of nine samples of copper tabulated one only is diamagnetic, again emphasising the difficulty of obtaining really non-magnetic conductors.

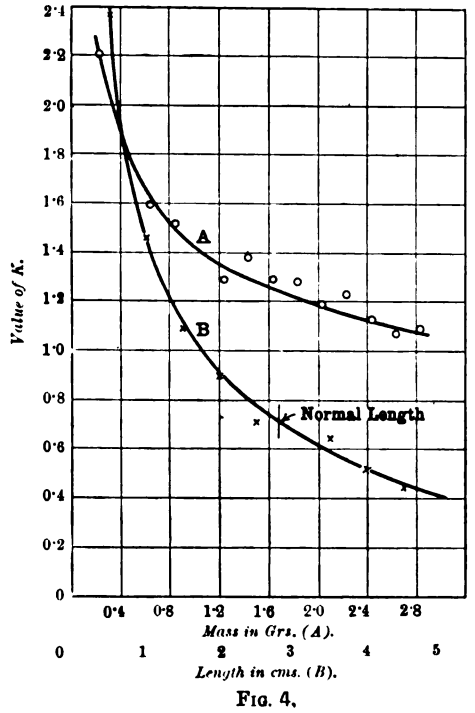

Fig. 4.

A point in connection with resistance alloys tested is the fact that every alloy is magnetic, but that those alloys containing relatively a large proportion of the magnetic metal nickel—*i.e.*, nickelines—are among the least so. The samples of platinoid fall into this group. The constantans come next in order. Eureka is a resistance material which is often classed as a constantan, but the balance easily disproves this, as it shows it to be so magnetic that observations would have had to be made with a stiffer suspension than we were using, and this, coupled with its positive temperature coefficient, rule it out of the group. The magnetic behaviour of manganin is remarkable. This is of particular interest in view of its almost universal adoption for the construction of accurate resistances, but it is not altogether unexpected when we remember that the remarkable Heusler alloys have a copper-aluminium manganese composition.

Another table in the Paper indicates the variation in the value of K with increase in mass of the specimen and increase in length. In the first case the sample, in the form of a bare wire 1 mm. in diameter, was cut up into standard length (approx. 2·8 cm.), and successive lengths of measured mass were introduced into the tube until it would hold no more; it will be observed that the value of K tends to diminish as the mass increases. (Curve A, Fig. 4.) The apparatus is, of course, very sensitive to the length of specimen, and an extreme range of length was taken in a wire of 1 mm. diameter, and the results are shown in curve B (copper).

Substance.	Density, Δ.	Coeff. of specific magnetisation, K.
Water	1·0	$-0{\cdot}79 \times 10^{-6}$
Alcohol	0·79	$-0{\cdot}78$
Benzene	0·85	$-0{\cdot}962$
Luxor oil	0·8	$-0{\cdot}594$
Aluminium (four samples)	2·67	$1{\cdot}19 \times 10^{-6}$ to $2{\cdot}99 \times 10^{-6}$
Brass (eleven samples)	8·1	$-0{\cdot}026 \times 10^{-6}$ to $+4{\cdot}05 \times 10^{-6}$
Copper (nine samples)	8·9	$-0{\cdot}097 \times 10^{-6}$ to $+1{\cdot}06 \times 10^{-6}$
Tin	7·3	$0{\cdot}151 \times 10^{-6}$
Zinc (three samples)	6·9	$0{\cdot}043 \times 10^{-6}$ to $0{\cdot}224 \times 10^{-6}$
Nickelin (four samples)	9·09 to 8·77	$2{\cdot}11 \times 10^{-6}$ to $5{\cdot}76 \times 10^{-6}$
Platinoid	8·83	$1{\cdot}75 \times 10^{-6}$
Constantan (four samples)	8·99	$9{\cdot}67 \times 10^{-6}$ to $12{\cdot}37 \times 10^{-6}$
German silver	9·06	$6{\cdot}77 \times 10^{-6}$
Manganin	8·61	$28{\cdot}05 \times 10^{-6}$

The difficulty of obtaining non-magnetic copper has already been referred to, and every instrument maker knows how difficult it is to wind a really non-magnetic D'Arsonval coil. In order to see how far this is dependent upon surface conditions, a sample of copper was taken and treated with concentrated hydrochloric acid and retested, and it was found that the value of K was reduced to nearly one-half, and that further treatment had but little effect.

From these results it will be seen that there is a considerable field of usefulness for the balance. Firstly, for examining the materials to be used in the construction of standard apparatus where the permeability becomes of first importance. Secondly, in grading and examining alloys whose properties are materially dependent upon minute traces of alloying constituents which are so difficult to estimate by chemical means, and which play such an important part in their electrical behaviour. Thirdly, it could well be used to maintain the standard of purity in the commercial production of such a metal as aluminium, whose chief impurity is iron, the last traces of which are so difficult to remove.

SOME PRACTICAL RESULTS OF THE USE OF CAR METERS.*

BY M. BATTES.

Summary.—After briefly summarising the progress that has been made in the use of car meters up to the present year, the reporter goes on to deal with the answers he has received to the *questionnaire*. It appears that great economies in money and energy consumption are derivable by the use of both clock and wattmeters, but the former class have the advantage of being cheaper in first cost and upkeep. The use of these instruments has allowed the average speed to be raised, but it is not known what effect they have on the number of accidents. The economies realisable are not set off by the greater cost of energy due to the higher speeds, nor are the motors adversely affected.

The subject of car meters was first dealt with by the Union Internationale de Tramways et de Chemins de Fer d'Intérêt Local at the Milan congress four years ago, Mr. Wattmann, of Frankfort, being the reporter. He pointed out that by the use of these instruments very good control of the energy consumption could be obtained, a view that was supported both by Mr. Otto, of Berlin, and by the present author at the congress at Munich two years ago.

Mr. Otto summed up his report on the results obtained up to 1908 by showing that the control of the motorman, whether it be by a clock or current meter, is a certain means of discovering the skill of the individual and of obtaining economies in energy consumption. On the other hand, as the results obtained with the clock meter possess the same practical value from the point of view of control as do those of the current meter, while the first cost, upkeep and adminis-

* Abstract of a report by Mr. Battes, general manager of the Frankfort tramways, on the replies received by the Union Internationale de Tramways et de Chemins de Fer d'Intérêt Local in response to the *questionnaire* sent out to the members, presented at the biennial meeting at Brussels (1910).

Digitized by Google

trative charges, necessary for the evaluation of the results, are much less in the case of these instruments than with the current meter, and that, further, the accuracy of the clock meter is certainly not less than that of the current meter, preference must, therefore, be given to it.

The Munich report concluded as follows: On systems of minor importance, good inspection may take the place of control by means of meters; the control of energy consumption by means of meters placed on the cars is recommended on all systems of any importance; such control becomes increasingly necessary as the service becomes more complicated, for the conditions under which the service is carried on in large towns, in the middle of dense traffic and where frequent stops are necessary, due to the great use of the tramways made by the public, require that the motormen should continually pay close attention to their work; control can be effected by watt-hour meters, ampere-hour meters or clock meters; as such control does not require that the absolute consumption of energy should be known, clock meters should be sufficient and are preferable, since they are accurate, simple and cheap; the office work necessary to evaluate the results obtained by the meters can be organised very simply and cheaply; the presentation of prizes for economical working is not recommended. The opinion was also expressed that the introduction of a good system of energy control would lead to a reduction in the number of accidents, and those members who had adopted these ideas were asked to give this point their particular attention.

In the *questionnaire*, on which the present report is based, stress was laid on the comparative results obtained by the use of current and clock meters and on the influence which the use of these meters has on the upkeep of the motors, whence it appears that the tests made during 1909 and 1910 indicate the special advantages of the clock meter.

At AMSTERDAM 235 clock meters have been installed since July, 1908, while up to that time the control of energy consumption had been effected experimentally by means of 75 clock meters and 21 wattmeters. It is considered that the clock meter is the simplest, least costly and most certain in operation. Tests have shown that wattmeters do not give accurate results and, further, require frequent and heavy repairs. The cost of installation of a clock meter, including fitting, is £2. 4s., the cost of repair is practically nil and the expenses of administration work out at about 0·0026d. per car-mile. The saving realised in 1909, as compared with the expenditure in 1906, was 11·5 per cent., while the consumption of energy per car-mile decreased from 0·876 to 0·776 units. It should be remarked, however, that part of this economy is due to the introduction of a better system of cleaning the rails.

At BERLIN, the success of a system of energy control has been very remarkable. The whole of the motor cars—that is to say, 1,491—have been equipped with clock meters since 1908. Comparative tests on a large scale, which have been carried out between wattmeters and clock meters, have shown that from the point of view of accurate results the two systems are about equivalent. On the other hand, the greater simplicity of the clock meters, their less first cost and cost of upkeep, and, above all, the great ease with which their readings can be understood by the motormen, have led this company to consider them superior to wattmeters. The first cost, including fitting, of a clock meter is about £2 in Berlin. Up to the present no upkeep costs have been incurred, as the instruments are still working under guarantee. The administration costs work out at about 0·004d. per car-mile. The application of the results obtained from the meters is very simple, being similar to that employed on the Frankfort tramways, and described in THE ELECTRICIAN, Vol. LIX., p. 252. The reduction in energy consumption in 1909 compared with that in 1907 was 7·8 per cent., which works out at an economy of £21,344, in spite of the fact that the average speed has been increased by 10 per cent.

At BERNE, 10 motor cars were fitted with clock meters in 1908. This step has led to an economy in energy consumption of 10 per cent. Meanwhile clock meters have been installed on the whole of the 41 motor cars now in service.

The results obtained at COLOGNE by the use of clock meters have been just as favourable as those set out above. As an experiment, 75 cars were fitted with these instruments in June, 1907, and as a result of the tests then made it was decided, at the beginning of 1909, similarly to equip the remaining 335 cars. Up to the present this system has worked quite well. The total first cost is £2. 1s. per car, the upkeep costs being about 0·0004d. per car-mile, and the administrative expenses about 0·01d. per car-mile. Control is effected in the same way as in Berlin. This system of control during 1909 has led to an economy of 0·072 unit per car-mile as compared with the energy consumed in 1908—*i.e.*, about 8·6 per cent. of the total consumption—in spite of the fact that during the course of the year 60 motor cars 1½ tons heavier and 140 trailers weighing 2·5 tons more than those formerly used were placed in service. Taking into account these extra weights it is calculated that the actual reduction in consumption due to car meters amounted to about 0·1 unit per car-mile. The amount saved in energy cost per month from April to December was £3,750, energy being purchased at a price of 0·85d. per unit.

At DUSSELDORF, all motor cars are now equipped with clock meters, the sole inconvenience complained of in these instruments being that they do not allow the time during which the motors are working in parallel to be determined. The first cost is about 35s. per car, the cost of upkeep and administration being 0·004d. per car-mile. It would seem that a saving in energy consumption of from 5 to 7 per cent. can be obtained, while on some of the newer cars after clock meters had been fitted the economy in energy was as much as 15 per cent.

At BARMEN-ELBERFELD, all cars built since 1908 have been equipped with clock instead of wattmeters. The cost is £2 per car, while wattmeters cost £7. 10s. No new results have been obtained during 1909, owing to the abnormal conditions of working.

At HAGEN, clock meters have been installed on all the motor cars for some years, but they were not used for controlling the energy consumption until May, 1909. Very bad results were obtained with wattmeters. An economy of 6 per cent. has been effected, though the clock system has only been in operation for a few months. The financial result is a saving of £323, the equipment of each car costing £2. 6s.

Clock meters were adopted on the GLADBACH tramways in 1907, and in this case, it is surprising to note, the first cost reached the high figure of £3. 2s. per car. A 4·3 per cent. saving in energy consumption was, however, effected, with a reduction in the working expenses of £350.

At NEUENBOURG unfavourable results were obtained with wattmeters, and clock meters were installed at the end of 1908. The first cost was £2. 16s. per car, and the economy in energy consumption 11·3 per cent.

At NUREMBURG-FÜRTH, where clock meters are also used, a saving in energy consumption of 6·2 per cent. was obtained, while the working costs were reduced by £650 per annum.

Similar results were obtained at PLAUEN, while clock meters, which were adopted at UTRECHT after comparative tests had been made, showed that, though all classes of meter work equally well, the first and upkeep costs were much less in the case of clock meters.

At VIENNA, all motor cars have been fitted with car meters since January of this year. This step was taken after comparative tests had been made between clock and wattmeters. The apparatus has been in use too short a time for any practical results to be obtained. Similar replies have been received from WIESBADEN and ZURICH.

From these replies it appears that a large number of undertakings have obtained excellent results, and have even notably improved their previous results by controlling their energy consumption with clock meters. On the other hand, control by wattmeters has but little developed.

In 1908, 126 motor cars in DRESDEN were fitted with wattmeters. In the interval the whole 504 motor cars have been so fitted, with successful results. The cost of installation is £3. 15s. per car.

The 19 motor cars in use on the MULHAUSEN tramways are still fitted with wattmeters. In 1908 it was reported that these worked badly, and that the motormen had lost confidence in them. Since then the construction of the apparatus has been improved. The economy obtained has been 10 per cent., but the instruments require constant inspection.

At STOCKHOLM, where in 1908 only 10 motor cars were fitted with watt meters, the whole are now so provided. An economy of 5·75 per cent. in current consumption has been obtained and reduction in expenses of £1,925. The first cost is £6. 17s. per car.

Of the numerous systems of control in use the reporter points out that that by ampere-hour meters has developed the least.

The BORDEAUX tramway company chose this type of meter after comparative tests. The whole of their cars have been provided with them since June, 1909, and they have proved satisfactory. Their first cost is £4. 5s., their upkeep 12s. 6d. and the administration expenses 0·009d. per car-mile. The control of the energy consumption has resulted in an economy of 10 per cent., or £1,600.

At MARSEILLES, where there are 400 motor-cars, 15 are fitted with clock meters and 10 with ampere-hour meters, but it has not yet been decided which of the two systems shall be adopted. Greater exactitude in the control of the energy consumed can be obtained than by using clock meters, while ampere-hour meters are preferred to wattmeters on account of their accuracy and construction. It has not been possible for any results to be given on the economies obtainable, as the tests have been too short and on too small a scale.

On the EAST PARIS tramways the whole of the 287 motor-cars are now fitted with ampere-hour meters. Previously, comparative

Digitized by Google

tests were made between wattmeters and clock meters. The first cost of the ampere-hour meters is £5. 13s. per car. On this system this class of meter has given excellent results, an economy of 7·27 per cent. in consumption having been obtained, corresponding to a saving of £2,419. The upkeep of these meters is 0·005d. per car-mile, and the administrative expenses are 0·009d. per car-mile.

From the results given above it appears that important systems cannot do without some sort of control over the energy consumed, while this control may be practically realised by means of some relatively simple apparatus. The different systems of control, whether by wattmeters, ampere-hour meters or clock meters, have given quite favourable results.

The majority of the companies who have answered the questions use clock meters, and these instruments have indubitably furnished results quite as good as either wattmeters or ampere-hour-meters. Besides, taking into account the importance of the financial results obtainable, the first cost and costs of upkeep, which are much higher for the last two types than for clock meters, can certainly be neglected, and each system may, therefore, be allowed the choice of determining what sort of instrument it should use.

The *questionnaire* inquired whether still further economies might be expected, taking into account the good results that had been generally obtained from the control of energy consumption. The majority of the members answered in the negative. It may be observed in this connection that on account of the growing increase in traffic, an increase in the energy consumption must also occur. This will inevitably reduce the percentage of economy obtained by the use of car meters. Some of the companies, however, hope to obtain still further economies than they have at present reached. In the opinion of the reporter there is a danger in laying too much stress on obtaining a great economy in energy consumption, for the motormen are thus incited to start contrary to reasonable orders that they have received.

As regards the question whether the use of car meters has led to a greater regularity of service, only a few of the companies have answered in the affirmative. No opinion is, therefore, expressed by the reporter on the point as to whether the control of energy consumption leads to a greater regularity in the service, either directly or indirectly. Directly, in the sense that motormen, observing the time the current is on or the energy consumption that has been fixed for certain sections of the route, are generally as regular as when they take into account the total operating time; indirectly, in the sense that the control of energy consumption allows the inspection of the motormen to be controlled in a closer manner.

In 1908 it was mentioned, in answer to a question by Mr. Hähner, of Strassburg, that the introduction of car meters permitted an increase in the commercial speed at Frankfort. Formerly, on account of the rule against increasing the maximum speed between consecutive stopping places, the motormen were led, in order to keep to the time-table, to prolong their waits at the termini. Control had, therefore, as a result, a decrease in the mean speed. It follows from this that the time allowed for travelling could be without inconvenience reduced by raising the former maxima speeds. The increase in rapidity of communication was very much appreciated by the public. General satisfaction has been caused by raising the mean speed from 7½ to 8¾ miles per hour and during the year 1908-09 a reduction in the running expenses of £13,000 from this cause alone has been obtained. Similar results have been obtained in Berlin.

These practical results and the accurate observations made in Frankfort on the increase of energy consumption owing to the increased commercial speed, contravert the false hypothesis formulated in Magdeburg, that the economies realisable in the running costs would be absorbed by the extra expense for energy.

Another question asked whether the employment of car meters exercised an unfavourable effect on the upkeep of the motors. This question was prompted by the fact that in certain places an assertion had been made that the economies realised in energy consumption were absorbed by repairing the motors, due to the new methods of working. It is interesting to notice from the answers given that only one company—and that of secondary magnitude—has stated that it is obliged to turn up the commutators more often than formerly. In general, no unfavourable influence on the upkeep of the motors has been noticed, while on certain large systems the use of car meters seems to have been favourable to their good operation.

The question, which was also asked, regarding how the number of accidents was affected by the use of car meters, is very difficult to answer. The number of accidents, in fact, depends on a series of circumstances, viz., the quality of the *personnel* and its professional education, the nature of the population in the different towns, the local circumstances of the track, the commercial speed, the braking arrangements, the operation of the brakes, the careful upkeep of the rolling stock and the general traffic conditions in the streets. It is, therefore, very hard to say whether a diminution in accidents is due to the use of car meters alone. Several answers state that the number of accidents has decreased since car meters were introduced, but they do not say in what proportion this diminution is due to the better methods of control. One single system alone states that the use of car meters has undoubtedly led to an important decrease in the number of accidents. Another member states that following on the use of clock meters the class of accidents which occurs to travellers at the moment they get on to the car will become more frequent. The reporter cannot subscribe to this opinion, which does not seem to be based on any fact.

As regards the improvements which it would be desirable to introduce into the various meters actually in use, attention may be called to one which is mentioned by most of the undertakings. It is that the current meters should register the energy consumption or the time during which the current is on separately for series and parallel working. Certain undertakings also think it would be useful to employ automatic apparatus to prevent the motormen from starting too quickly. However justified these desiderata may be under certain conditions, care should be taken not to interfere with personal control too much, or else the remedy will tend to become worse than the disease. In this connection it may be mentioned that the Hagen undertaking report that they have put into service a ratchet arrangement for working the controllers. It would be interesting to know later on how this behaves in practice. Brussels, too, employ with great success a system of so-called automatic starting resistances.

A special question which was introduced into the *questionnaire* at the request of Mr. Bouton, seems to have rather lost its purpose on account of the results described above. Even before the introduction of current control all the undertakings had dealt with motormen who started too rapidly. Passengers, too, exercise an excellent control in this respect, as they would not tolerate the continual disadvantages occasioned by starting too quickly. Before the adoption of current control the motormen were inclined to diminish the running time in order to increase the waits at the termini. In this respect, too, the use of wattmeters and ammeters have a disadvantage. When the motors are started too rapidly the resistances are cut out of circuit quickly. In consequence, the losses in the resistances are diminished, and an increase in the useful effect during the period of acceleration is obtained. Well-standardised wattmeters and ammeters, therefore, tend to render the motorman less conscientious in starting at an exaggerated speed than is the case with the clock meters. If it is considered that in the case of rapid starting the motor meter, on account of its armature, gives results which do not correspond to the absolute values because it cannot follow immediately the rapid increase in current or electrical work, one is led to the conclusion that this reproach, which has been made specially against clock meters, is not justified. Besides, the motorman who habitually starts too rapidly is soon discovered, from the fact that his figures for energy consumption are much less than the mean value. In the reporter's opinion this inconvenience is relatively easy to avoid, notably by giving instructions to the motormen that they must keep their consumption as far as possible in the neighbourhood of the mean value and by not inciting them by the inopportune inspection to try and obtain figures which are favourable in appearance. It may be admitted that in general after proper instruction motormen will do this conscientiously. Some motormen, of course, to whom all control is an annoyance, will be disposed to commit intentional faults in starting in the hope of lowering the good name of the system in the eyes of the public and in the hope of doing away also with this system of control.

From the answers received to the last question of the *questionnaire* it appears that most of the systems are content with simply watching more closely such motormen as consume energy in a spendthrift way and to give them further instruction. Many of the others obtain the same end by working on the self-respect of their men, and by bringing to the knowledge of the *personnel* at more or less regular intervals the names of the best and the worst motormen. Some systems reward their best motormen by making them teach new comers. The majority of the systems are not in favour of punishment, which they consider as inefficacious.

Electric Cooking on War Vessels.—According to the "Electrical World," after elaborate tests the United States Navy Department have installed electric ranges and electric bakers on the "Dixie," and is considering electric cooking upon practically all their battleships and cruisers. The tests of these cooking devices were made at the Navy bakery school, near Newport, R.I.

ILLUMINATION REQUIREMENTS IN STREET LIGHTING.*

BY A. J. SWEET.

Summary.—The author first discusses the requirements of street illumination and the avoidance of glare, and then proceeds to investigate the distribution curve necessary for a source of light in order that a practically uniform horizontal illumination (within limits of 1:4) may result. Some interesting investigations on the relation between glare effect and distance, between glare effect and candle-power, and between glare effect and angular position of the light source are described.

There are two results to be achieved in adequate street illumination, both of such paramount importance that it is properly a matter for individual opinion as to which should be ranked first. These are the avoidance of glare effect and the obtaining of an approximately uniform degree of illumination at all points along the course of the street, with higher intensities at street corners. These two results can only be obtained, the one by the correct solution of the allied problems of intrinsic brilliancy, total light flux and shadow contrasts, the other by the correct solution of the problem of distribution. Let us consider each of the results sought and define it a little more exactly.

Glare effect results whenever, throughout any infinitesimal period of time, an amount of light continues to fall upon the actively visualising portion of the retina of the eye sufficient in quantity to cause chemical changes more rapidly than the regenerative functions of the eye can keep pace with. Thus, when an eye, which has been exposed for some time to conditions of dark with resultant pupillary expansion, is suddenly exposed to even a moderate light, glare effect results. An excessive amount of light reaches the retina through the expanded pupil, and the regenerative functions cannot keep pace with the chemical changes induced. Rapidly, however, the pupil contracts, the regenerative functions regain their normal control, and the glare effect passes away. If now the eye be exposed to a still greater intensity of light, beyond the very limited capacity of pupillary contraction to compensate for, or if an even moderately bright light source is introduced near the centre of the field of vision, glare effect is again experienced; and this glare effect, after a brief period, reaches a certain state of equilibrium characterised by a quite definite decrease in efficiency of vision, which decrease thereafter increases in magnitude only rather slowly. We may, therefore, for convenience designate a glare condition as casual when it results from the inability of the pupil to adjust itself instantly to a changed condition of light intensity, and as fundamental when it results from a light intensity exceeding the contractive power of the pupil to compensate for, or when it results from a light source near the centre of the field of vision. The presence of strong shadow contrasts tends to produce a casual condition of glare. The evil effect of the shadow contrast lies in the demand it introduces for instantaneous pupillary changes of considerable magnitude when the eye is turned from the shaded to the unshaded area, or vice versa. In street lighting, this casual condition of glare is much less objectionable to the slowly moving pedestrian than to the more rapidly moving automobilist or carriage driver. It is usually sufficient, therefore, to throw the shadows toward the sidewalk and to provide against too deep shadows. The avoidance of objectionably-located shadow contrasts can only be taken care of by the proper placement of the light sources, while the intensity of the shadow contrast can be decreased by using smaller light sources placed nearer together. The problem of shadow contrasts, while of considerable importance, is one that must be solved individually for each individual case.

Brilliant, high candle-power light sources in the field of vision, the usual practice in contemporary street lighting, produce a fundamental condition of glare, with resultant heavy decrease in efficiency of vision—with probably also, be it noted, a permanently injurious effect on the faculty of vision. This fundamental condition of glare arises from the intrinsic brilliancy and total light flux of the light units employed and can only be avoided by the proper limitation of these. The study of the relations existing between intrinsic brilliancy and total light flux on the one hand, and glare effect on the other, becomes, therefore, one of the two chief purposes of an analysis of the illumination requirements of street lighting. The end sought should be the elimination of glare effect, or at least its reduction to such a permissible minimum as will not seriously decrease the efficiency of vision nor be sufficient to produce eye discomfort.

The derivation of the polar curves of light distribution which will give the proper relative intensity of illumination for points along the course of the street is, as has already been noted, the second of the two chief purposes of an analysis of illumination requirements in street lighting. Here the end sought is the uniform illumination of all points along the course of the street. At street intersections and similar crossings a brighter illumination is needed, of course. This should be of from four to eight times the intensity of the illumination along the main course of the street. Such brighter illumination is properly provided for by employing from four to eight light units each having the same light distribution as the units used along the course of the street, or by one or two light units of similar light distribution and larger size. The street intersection, therefore, presents no complication to our problem, and its proper treatment becomes merely a matter for adequate consideration at the time of installation.

The statement is often heard that in street lighting absolute uniformity of illumination is not required, or is of any particular importance. Taken in a very strict sense, this statement contains much truth. A ratio of maximum to minimum intensity of 4 to 1 is permissible; but the ratio in present practice most frequently falls between 100 to 1 and 500 to 1.

Another much-mooted question concerns the way in which illumination should be measured, whether horizontally or perpendicular to the light ray. The latter method has been largely adopted in American practice chiefly through the influence of the commercial interests concerned, who desire to make the minimum value look as large as possible. The horizontal plane, which is the accepted reference plane in interior lighting, is the logical and most satisfactory basis for street illumination measurements.

The ideal to be aimed at, therefore, in street lighting, as far as intensity is concerned, is uniform horizontal illumination. On this basis we can proceed to derive the ideal curves of light distribution. These curves once derived, we may properly take into account the fact that absolute uniformity is not of importance; and we shall only ask that the actual light distribution sought for as a practical ideal shall show no greater variation from our theoretical ideal than 4 to 1 in ratio of maximum positive variation to maximum negative variation, as read in percentage values of the theoretical curve along the corresponding angles.

☆ ☆ ☆ ☆ ☆ ☆ ☆

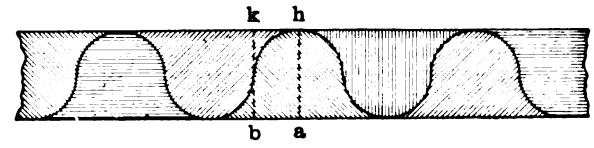

FIG. 1

The nature of a street makes most natural a placement of light units as a line of single units extending along the street, the units being hung over the centre of the roadway or located alternately on either side. For all practical purposes, these two cases can be treated as one, the separation of adjacent units being taken as the straight line distance between the units, and the distribution curve derived being the correct distribution in a vertical plane passing through the unit concerned and the adjacent unit. There are an infinite number of light distributions which will give uniform illumination from a line of light units along a line extending immediately under those units. Other considerations than the obtaining of uniformity must therefore serve to enable us to select the most desirable distribution curve.

Two such considerations are of especial importance and may therefore be applied with especial propriety. First, we should seek a distribution as will be best suited for actual, practical attainment. This consideration is of the more importance because, as we shall find, even when maximum weight is given to this consideration, our derived curve will present considerable, though by no means insurmountable, difficulties of practical realisation. Second, the illumination at any point should be derived from a source as near as possible in order to avoid both excessively long shadows and the glare effect which results from the high candle-power made necessary by illumination at great distances.

Various illumination curves are illustrated in the Paper. The author states that it can be shown mathematically that the curve which best meets the conditions is as shown in Fig. 1. This curve is formed by two circle quadrants. The corresponding distribution curve shows a low maximum which occurs at a slightly smaller angle than that subtended by half the separation of the units. It is also as well adaptable to practical realisation as any curve obtainable.

We have, therefore, obtained the ideal illumination curve from which the desired distribution curve can be easily derived.

* Abstract of a Paper read at a meeting of the Franklin Institute, Philadelphia.

Digitized by Google

The relation between any desired illumination results and the distribution required to produce those results depends, in the type of problem under consideration, upon: (*a*) The distance between adjacent units; (*b*) the height of the light unit above the street. It is obvious that any given distribution curve will give the same proportionate illumination so long as the relation between the separation of units and the height above street is kept constant. We can combine, therefore, the factors (*a*) and (*b*), and say that the distribution required to produce any given illumination result depends upon the relation between (*a*) and (*b*). Let us call this relation $M = \frac{\text{distance between adjacent light units}}{\text{height of light unit above street}}$. For any value of M there is a given distribution curve which will produce the desired illumination result.

Present-day street lighting practice shows a wide variation in the value of M. In the large cities of America the values of M vary from M=5 to M=31. The smaller cities would probably show in general a higher value for M than the large cities. All

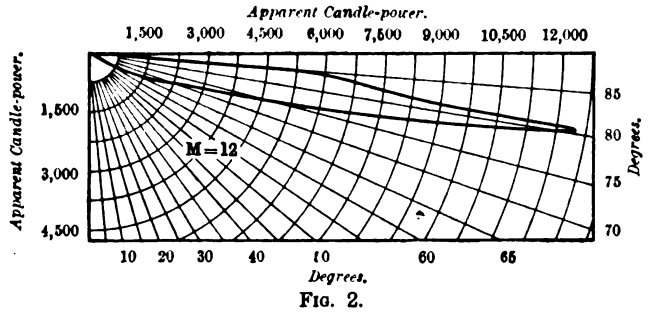

FIG. 2.

things considered, a value M=15 can probably be taken as the most representative value of present-day American practice, with a marked tendency towards smaller values in the more recent installations.

Fig. 2 shows the distribution curve required to produce uniform illumination when M=12. Such a curve, of course, is impractical for actual realisation, and would be extremely undesirable, even if it were practical to obtain it, on account of the excessive glare effect resulting from the very high candle-power maximum at a large angle. Fig. 2 serves one excellent purpose. It shows beyond argument that, with a value M=12 or greater, any attempt at adequate street lighting is absurd. If ignorance and a false economy compel an installation value of M=12 or greater, the pretence of obtaining "street illumination" should frankly be abandoned. Instead, the lights should be installed on the basis of a system of street markers, and located where they will best serve as markers. In such case, maximum usefulness as markers will be obtained when the candle-power values at the different angles are as close as pos-

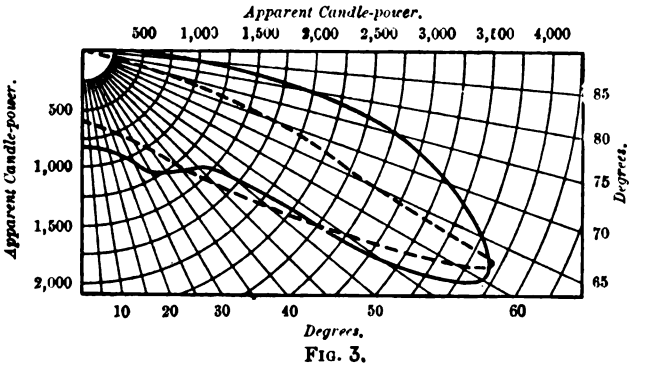

FIG. 3.

sible to, yet not exceeding, the limits imposed by the avoidance of glare effect. Be it noted that in sparsely settled districts, where the very slight use of the streets by night may not warrant adequate street illumination, such a system of markers has a very real field of usefulness.

The required distribution curves for M=8, M=6 and M=4 are given by the author. The latter two are quite practical. For instance, the full-line curve in Fig. 3 shows the actual distribution of one make of arc lamp to-day on the market, whilst the dotted curve is the ideal curve for M=4. It will be seen that the agreement of the two curves is admirable up to an angle of about 62 deg. The curves M=4 and M=6 would also be comparatively easy of attainment with the incandescent lamp or with the inverted gas mantle. This is of especial importance since, with these lower values of M, such smaller units give amply sufficient intensity of illumination except in those business centres where night traffic is considerable.

Smaller values for M than 4 would obviously fulfill all the conditions imposed by the requirements of good illumination. It is shown later in connection with glare that a value M=3 is necessary to obtain best results whenever, on account of shaded conditions of street or other considerations, it is desirable to mount the units at a height of 15 ft. or less above the street.

Thus far we have considered distribution only as referred to the vertical plane passing through the light unit and its adjacent unit. We will now consider the vertical plane perpendicular to the street line. In those rare instances where the width of the street from property line to property line is greater than the separation of adjacent units, the ideal distribution in this latter plane is similar, for the lesser angles, to the distribution required by the existing value of M. It continues, however, to a higher maximum, turning and receding rapidly to zero above the angle subtended by the distance from the light unit to the more distant property line. When the street width is not greater than the separation nor less than three-fourths of the separation, the distribution in the plane across the street should be approximately the same as in the plane

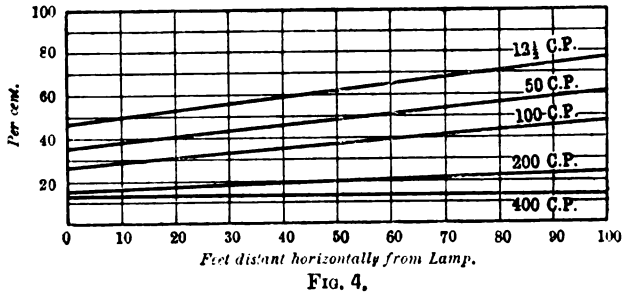

FIG. 4.

through the light units. When the street width is less than three-fourths of the separation, the distribution in the plane across the street is similar, for the lesser angles, to the distribution required by the existing value of M.

The second great division of our subject, the study of glare effect, has already been introduced in general terms in the earlier portion of this Paper. It now remains to analyse glare effect closely, to determine the laws of operation of the conditions that produce it, and to learn the limitations which it imposes on our problem. Avoidance of glare effect will operate by imposing a definite candle-power limit at each distribution angle, this limit varying only with the mounting height. In proportion as this candle-power limit is exceeded a greater or less glare effect will result.

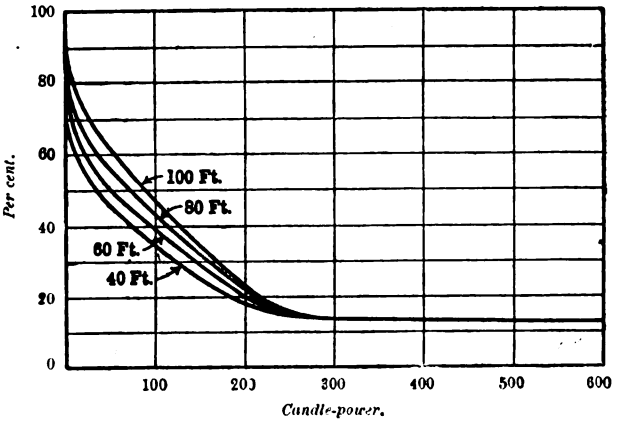

FIG. 5.

Subject to confirmation by research results, glare effect may be assumed to vary with the following factors: (*a*) Distance of the eye from the light source; (*b*) total light flux in the direction of the eye, this being measured in apparent candle-power at the distance of the eye; (*c*) intrinsic brilliancy of the light source; (*d*) angular position of the light source in the field of vision, the visualised object being assumed to occupy the centre of the field of vision; (*e*) distance of the light source from the eye relative to the distance of the visualised object upon which the eye is focussed.

In the present research the factor (*a*) was separately studied and determined with sufficient exactness to indicate reliably its character and approximate magnitude for distances up to 100 ft. Factors (*b*) and (*c*) were studied unseparated, as a single factor, the light flux varying directly as the intrinsic brilliancy. Factor (*d*) was separately studied and evaluated. Factor (*e*) was not investigated, the distance of the light source from the eye being in all cases taken

Digitized by Google

as equal to the distance of the visualised object. This condition corresponds to the most usual condition of actual street vision.

Heretofore no satisfactory measure of glare effect has been proposed. Since we are dealing with a psychological phenomenon, the basis of measure must obviously be a psychological one. On the other hand, the measure must be expressible in definite numerical units. A basis of measure fulfilling these requirements was conceived of for this investigation and proved a very satisfactory one. Preliminary to a more detailed description, such a measure may be described as the ratio of the two minimum light intensities on the visualised object, of magnitude just sufficient to enable its discernment, when the eye was successively exposed to the two conditions under comparison. A careful preliminary investigation established the fact that, under widely varying daylight conditions, visual acuity was wholly independent of distance, within the limits investigated: that is to say, with any given type of visualised object, the minimum size of object which can be just barely distinguished as a separate unity is exactly proportional to the visual distance. Three different test-plates were employed. In these test-plates each object or unit gradation is 10 per cent. smaller than the one previous. After establishing the fact just stated, each observer was calibrated, the determination being made of the minimum unit gradation which could be individualised under daylight conditions at various standard test distances. The fourth larger gradation was then chosen as the test object at the corresponding distance in the glare tests. This made it certain that the test objects were, by a uniform amount, well within the limits of visual acuity under adequate conditions of illumination. Consequently the ability to visualise these objects was wholly determined by the visual efficiency of the eye and by the intensity of illumination on the object. Expressed mathematically, we are here dealing with a constant which is a function of two variables. One variable, therefore, the minimum intensity of illumination on the object

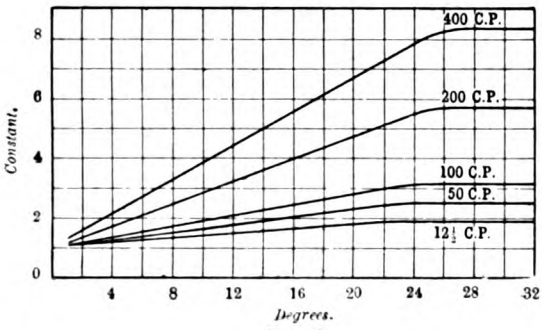

FIG. 6.

required to produce just-visibility, may be correctly employed as a measure of the other variable, the efficiency of the eye under any given condition. [The author believes that this basis of measurement is a very satisfactory one and has a wide field of usefulness in future investigations of this character.]

The basis of measurement being established, tests were first made to determine the relation between distance of the light source from the eye and the magnitude of the decrease in visual efficiency due to glare. These tests were made at five test stations, three independent sets of readings, one with each test plate, being taken at each station. Parallel tests were made with different observers. The complete series was then repeated with each observer, using various other candle-power intensities of the light source. The area of the light source throughout all these tests was kept constant, at about 50 sq. in., the intrinsic brilliancy thus varying directly with the candle-power, as has already been stated.

Fig. 4 expresses the relation between glare effect and distance, the light unit being situated beside the visualised object in the centre of the field of vision. The ordinates express visual efficiency in terms of the per cent. intensity of illumination on the visualised object which would be required for equal visual acuity were the light source entirely removed from the field of vision. It will be noted that at 12½ c.p. and an intrinsic brilliancy of 0·25, the glare effect drops off at a moderate rate with increase in distance. At higher candle-powers and higher intrinsic brilliancy, the glare effect decreases more slowly with increase in distance; until finally, at 400 c.p. and an intrinsic brilliancy of 8, there is no measurable decrease in glare effect with increase in distance within the limits investigated.

Fig. 5, derived from the same test data, expresses the relation between glare effect and candle-power (or, as it may be instead, between glare effect and intrinsic brilliancy). These curves are especially significant. It will be seen that, for all ordinary distances, the presence of a light source of even a very low candle-power in the centre of the field of vision causes a tremendous drop in visual efficiency. It will also be noted that at 300 c.p. the glare effect has nearly reached its maximum, and that beyond 300 c.p. a large increase in candle-power produces but a small decrease in visual efficiency. Finally, one should not fail to observe that at any given candle-power a considerable increase in distance produces only a small decrease in glare effect.

The relation between glare effect and the angular position of the light source in the field of vision was determined by a series of tests similar in general method to the tests already described. The amount of illumination required to see the test object when the light source was in the angular position was compared with the amount required when the light source was in the centre of the field of vision. The results obtained are shown in Fig. 6. The ordinates here express the intensity of illumination required with the light source in the centre of the field of vision as measured in terms of the

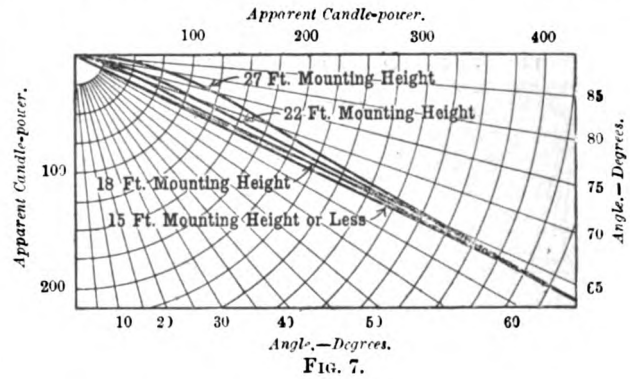

FIG. 7.

required intensity with the light source in the indicated angular position. The abscissæ in Fig. 6 represent the angles which the line from the light source to the eye makes with the line of vision.

The curves of Fig. 6 express a fact of the very highest importance in the study of glare, namely, that, at an angle varying, depending on the candle-power (intrinsic brilliancy ?), between approximately 22 deg. and approximately 26 deg. the glare effect reaches zero, although the light source is still well within the field of vision. This would seem to indicate that on its physiological side glare effect is a local retinal disturbance which, when sufficiently separated on the retina from the disturbance produced by the visualised object, does not extend to or affect the latter area of disturbance. This apparent fact seems to hold true even when a considerable time factor is introduced. Apparently pupillary contraction acts merely as a function protecting, within its very limited capacity, from a glare effect more or less suffused over the whole retina. The writer has

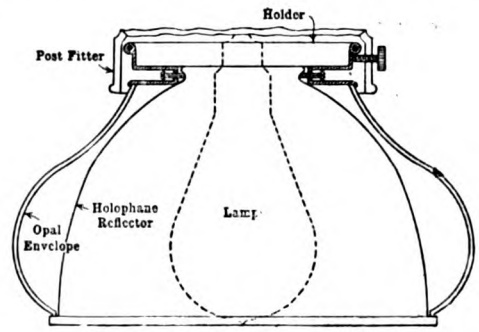

FIG. 8.

previously believed that pupillary contraction was in itself a cause of decreased visual efficiency in that, on account of pupillary contraction, a lesser amount of light would be admitted to the retina from the visualised object. He now believes that pupillary contraction should be regarded as a purely protective function and not, through its operation, in any sense itself a cause of decreased visual efficiency.

The practical importance attaching to these facts is of no less vital interest than the scientific. Fig. 6 means that the light instrumental in causing glare comes entirely from the polar angles above 60 deg. In the average actual case, glare is almost wholly caused by the light between the angles of 65 deg. and 80 deg. with the nadir. The light within these angles must be partially or wholly suppressed, as the further facts of the case will show to be required, if glare is to be avoided.

Digitized by Google

We have already discussed the operation of the curve of zero glare effect in eliminating certain curves of distribution. We are now in a position to determine the true curves of zero glare effect, which, as will be remembered, will vary somewhat with the mounting height.

Fig. 7, derived from Figs. 4 and 6, gives the curves of zero glare effect for various mounting heights. Comparing these curves with the curve of ideal distribution when M=6, we see at once that this curve, together with curves of larger value of M, will be eliminated on account of the serious glare effect which would result from the application of such distributions to actual practice. The curve M=4, however, comes within the limitations imposed by the curve

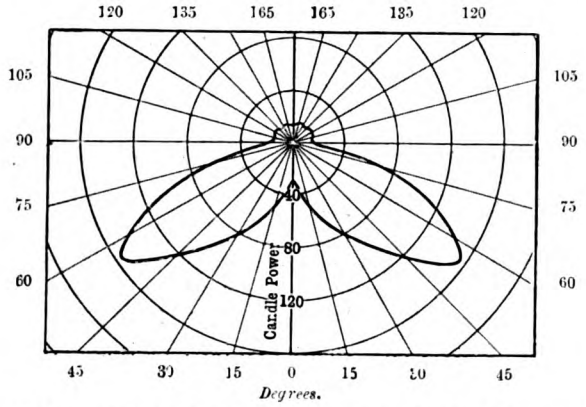

FIG. 9.—DISTRIBUTION GIVEN BY HOLOPHANE STREET LIGHTING UNIT WITH STANDARD 100 WATT 110 VOLT MULTIPLE LAMP.

of zero glare effect, providing the scale of the M=4 curve does not exceed that amount which would make the zero-degree candle-power equal to 100 c.p. The distribution curve corresponding to M=3 would come well within the limitiations imposed by zero glare.

Reference to Fig. 7 shows that for all practical purposes, 60 deg. is an absolute limit for maximum candle-power if serious glare effect is to be avoided. It will also be observed that an increase in mounting height, while it does not change the limiting angle for maximum candle-power, does considerably lighten the severity of the limitations at 65 deg. and above. Mounting heights of the larger values, when made possible by actual conditions, are also desirable as permitting wider separation of units with resultant decreased installation and maintenance cost. For mounting heights of 15 ft. or less, the curve M=4 will produce considerable glare, beyond,

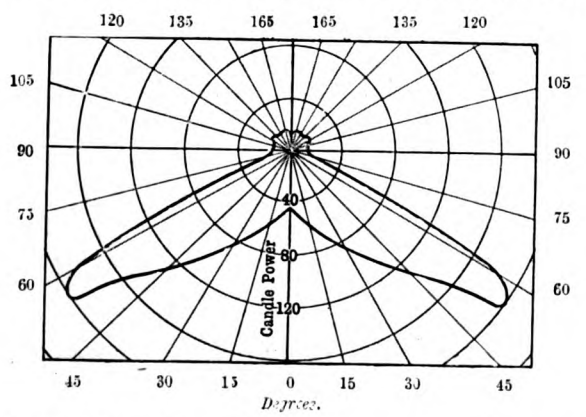

FIG. 10.—DISTRIBUTION GIVEN BY HOLOPHANE STREET LIGHTING UNIT WITH SPECIAL 100 WATT 5·5 AMP. SERIES LAMP.

indeed, what proper limitations can permit. For such lesser mounting heights, as has already been pointed out, a closer spacing of units and a distribution corresponding to the curve M=3 should be used.

In designing a light unit to give the desired distribution which has largest field of application, namely, the distribution from M=4, it will be preferable by far that the candle-power values at 60 deg. and above, be less than those made proper by the ideal curve, rather than that these ideal values be exceeded. With an ideal curve of such candle-power magnitude as would be most useful, the candle-power values at the angles under consideration come perilously near to the glare limit, or may even exceed the glare limit. A per cent. variation from the ideal curve of four to one is, as has been pointed out, permissible. Even a moderate condition of glare, on the other hand, is very undesirable. Practical considerations, therefore, will lead us, in the design of the actual unit, to deviate intentionally from the M=4 curve at angles of 60 deg. and above, this devitaion being in the direction of lesser candle-power values.

It is of the utmost importance to note that if the glare limit is exceeded at all, it will almost of necessity be exceeded excessively. The curve of zero glare-effect runs almost instantly back to zero near the angle of 65 deg. The glare-effect would therefore increase with great rapidity as an angle of 65 deg. was exceeded. The curves required for uniform illumination, on the other hand, increase with great rapidity in candle-power values to their point of turning. It is obvious that the curve of zero glare effect must be taken as a line of absolute prohibition. If it is to be exceeded at all, it may as well be entirely ignored. For an apparently small violation of the limit will produce a decrease in visual efficiency of approximately the same order of magnitude as the maximum possible effect.

It is also of great importance to note that the curve of ideal distribution for M=4 remains, though not an ideal, yet none the less the best possible curve when applied to actual conditions where M has a larger value than 4. The curve M=4 gives the best spot-lighting effect and the best marker-effect which are possible without engendering a condition of glare. This research has indicated that, for ordinary mounting heights, moderate glare is a mere name: the reality is always excessive glare. It is the opinion of the writer, therefore, that glare must be avoided, even if so important a consideration as proper distribution has to be sacrificed. And indeed, as has been shown, other conditions than glare make a proper distribution impractical or even impossible with the larger values of M. The curve M=4 is to be regarded, therefore, not merely as the ideal curve for a certain relatively close spacing of light units which the public is not as yet educated up to, but as the best possible distribution which can be applied to any of our present-day spacings. This Paper is not presented, therefore, as merely expressing an ideal to be approximated to in a comparatively remote future. Rather, it should serve as a guide of immediate usefulness and application to present-day practice. The ordinary citizen of to-day, however, uses in his ignorance the very defect itself, the glaring character of a street illuminant, as a measure of its excellence. Such ordinary citizen would consider himself defrauded were he called upon to pay through his taxes for a street illumination characterised by absence of glare, by light on the street itself and not in the eye.

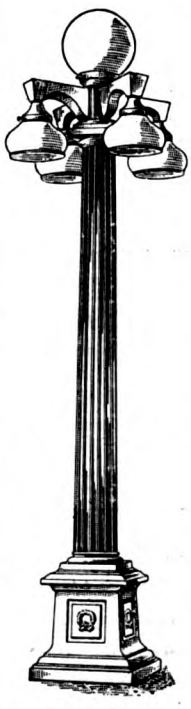

FIG. 11.

In the current issue of the "Illuminating Engineer," of New York, Mr. A. J. Sweet, after enumerating the requirements of street lighting, as set out above, describes a new combination diffusing and reflecting unit for use with a tungsten lamp. The construction of this unit is shown in Fig. 8 herewith. It consists essentially of a Holophane prismatic reflector surrounded by an outside opal envelope, the two being held together by a suitable metal holder. The primary function of the opal envelope is to protect the reflector prisms from dirt deposit which, in the presence of the mositure incident to out-of-door service, would cut down the reflecting efficiency of the prisms. A metal envelope might, of course, be used to accomplish the same purpose, but it is considered desirable that the unit be visible by night, both on account of artistic considerations and in order to afford a marked effect along the course of the street.

When used with the standard multiple lamp this unit, the author claims, gives a materially lower degree of glare than any other unit of equal illuminating power with which he is acquainted. The several large manufacturers of tungsten lamps are now seeking to develop a special series lamp, and when this has been satisfactorily worked out it is believed that a street lighting unit giving complete absence of glare will be produced.

The curves of distribution of the present unit are shown in Figs. 9 and 10. Its appearance in service in connection with a modern lamp-post is shown in Fig. 11.

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement was published (Gratis) with the number of "THE ELECTRICIAN" for September 23.

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various industrial purposes.

SPECIAL NOTICE.

NOW READY.—Vol. LXIV. of "THE ELECTRICIAN" (1,086 pages), bound in strong cloth. Price 17s. 6d.; post free, 18s. 6d. Now ready. Cases for Binding. Price 2s.; post free, 2s. 3d.

A complete set of "THE ELECTRICIAN" can be supplied. A number of odd volumes and some odd old back numbers, to help in making up complete sets, are also available.

ENERGY CONSUMPTION ON TRAMWAYS.

An examination of the statistical records of electric tramways for the past year, together with the reports of the general managers of the undertakings, shows that in several cases economies have been found possible in the consumption of electrical energy, apart from any saving due to lower charges being made for current supplied by the electricity departments. A short time ago it was the general experience that the number of units used per car-mile had a tendency to increase—in many cases owing to the use of heavier cars with top covers and to the growth of traffic—but of recent years, owing to the disappointing financial returns shown by many undertakings, considerable attention has been paid to checking any such tendency and to reducing the working expenses generally of tramways. This has led to a careful scrutiny of all items of expense; and on that account efforts have frequently been concentrated on obtaining a lower charge for the electrical energy purchased. In some instances, undoubtedly, a lower charge is justified, and it would tend to harmonious working if it were possible to agree upon a uniform method of calculating the charge for energy. Though, if the true cost of generating the electrical energy is to form the sole basis of calculation, together with the respective capital charges, as has already been arranged by some electricity and tramway committees, this to some extent ignores the

Digitized by Google

factor for the due observance of which Mr. E. W. COWAN is energetically pleading, namely, the character and intensity of the demand.

In the case of a large undertaking a small reduction in the price per unit at which current is purchased means a considerable sum when reckoned on the total number of units used; but it must not be forgotten that equally satisfactory results can be obtained by even small economies in the energy consumed per car. In this connection, encouraging results have been obtained in this country, as well as abroad, by instructing the motormen in the handling of their cars in a more careful manner and by installing meters so that a complete check can be obtained on the energy consumption of individual cars. To Mr. R. S. PILCHER, general manager of the Aberdeen Corporation Tramways, belongs the credit of being one of the first to appreciate the benefits likely to accrue from systematic instruction of the motormen. In a Paper read last year before the Municipal Tramways Association, Mr. PILCHER called attention to this subject, and further particulars of the results achieved at Aberdeen are contained in his annual report, for the year ended May 31st last, on the tramways of that city. A curve given in this report shows how the energy consumption on the Aberdeen tramways steadily increased from 1·05 units per car-mile in 1903 to a maximum of 1·328 units in 1906. At that date instruction of the motormen was introduced, and was followed by the installation of car-meters. The result is that the consumption has now decreased to 1·182 units per car-mile, notwithstanding that a large proportion of the cars have been fitted with top covers during this period. It is interesting to notice that Mr. PILCHER believes the minimum point of energy consumption has now been reached. It must also not be forgotten that a saving over and above that shown in energy consumption is obtained where meters have been installed, since there is considerably less wear and tear upon the gear and equipment of the cars, particularly as regards brake blocks. In fact, the full effects of more careful driving are likely to become apparent to a still greater extent in the future when the repairs and maintenance item is considered.

Further striking evidence of the saving in energy brought about by the employment of meters on tramcars is provided in the annual report of Mr. L. E. HARVEY on the working of the South Shields Corporation tramway undertaking. Up to the end of November last the energy used by the cars averaged 1·363 units per car-mile. Meters had been installed on all cars by that date, but owing to the necessity of the men having to be trained to economise energy, and also owing to the exceptional climatic conditions prevailing, the full effect of the meters did not become apparent for the next two months. In February of the present year, however, the energy consumption had decreased to 1·196 units per car-mile and in March to 1·188 units, a reduction of about 13 per cent. on the figure recorded before the installation of the meters. Although, of course, it is impossible to compare the energy consumption on two tramways without full consideration of all the particulars of their equipment and operation, it is interesting, nevertheless, to notice how these figures resemble those at Aberdeen, both as regards energy consumption and the saving obtained by the use of meters. In fact, the experience at Aberdeen and South Shields is typical of the results achieved elsewhere, and emphasises the importance of keeping records of this kind.

Although during the last year or two much greater interest has been taken in the advantages to be derived from recording the energy consumption of each car, as is shown to some extent by the number of meters in use (in this connection reference may be made to "The Electrician" Annual Tables of Electric Tramway Undertakings), it is rather curious to notice that many of the largest undertakings in this country appear to have done very little experimenting, or, at any rate, have few, if any, meters in use. The most striking instance, of course, is that of the London County Council tramways. The emergencies of London traffic to some extent prevent the motormen from exercising that care which would be possible under other conditions; nevertheless, there would certainly seem to be a need for recording the energy consumption, since it is noticeable that "coasting" is rarely practised by the motormen. On the other hand, if we turn to Continental tramways it will be found that extensive experience has been gained for some years on most of the important undertakings, and the subject has been carefully investigated by the Union Internationale de Tramways et de Chemins de Fer d'Intérêt Local. At the Congress of this Society at Brussels during the present month two reports on car meters were submitted; the first by Mr. BATTES, general manager of the Frankfort-on-Main Corporation Tramways, and the other by Mr. BOUTON, of the East Paris Tramway Co. Elsewhere in the present issue we give an abstract of Mr. BATTES' report, and we hope to give an abstract of Mr. BOUTON'S report in a subsequent issue. Both of these reports should prove very valuable to English tramway managers. It will be remembered that at previous congresses reports have been presented by Messrs. OTTO and BATTES, and it was owing to the desirability of collecting further information and reaching, if possible, final conclusions that the present reports have been prepared. Mr. BATTES reports that watt-hour, ampere-hour and the clock type of meter appear to be giving satisfactory results, but the clock type is generally preferred. Mr. BOUTON is in favour of the ampere-hour type under the following conditions:—where a bonus system is under consideration, where it is difficult to supervise drivers, wherever stops are frequent, cars are heavy, curves are numerous, gradients steep and current is expensive. Under other circumstances the use of time meters is recommended, except in the case of small undertakings. It is worth noting that the subject is also being considered in America, and the abstract of a Paper by Mr. H. St. C. PUTNAM, which is given on another page, should prove of interest to engineers. In fact, a wealth of information is now available, and it is noteworthy that it practically all points to the importance of recording and checking the energy consumption of individual cars.

Reverting, in conclusion, to practice in this country, most tramway managers now appreciate the value of diagrams for conveying at a glance information which would otherwise be buried in a mass of statistics, and they frequently attach to their annual reports diagrams showing the traffic, receipts, etc., throughout the year.

Digitized by Google

Some of the clearest and most interesting diagrams of this nature that we have seen are included by Mr. W. M. ROGERSON in his annual report on the progress of the Halifax Corporation Tramways; and we may mention, as one of the most interesting, the diagram illustrating the weekly consumption of electrical energy per car-mile. The variation of this item throughout the year, especially when the records for several years are included on the same diagram, is certainly most instructive. This variation is, of course, to some extent affected by the traffic peculiarities of each particular town. In the case of Halifax we notice that the curve for the past year lies considerably below those of the previous two years, the minimum consumption, viz., 1·74 units per car-mile, being recorded during three consecutive weeks in September, 1909, and the maximum of 2·05 units being reached early in April, 1909—the week preceding Easter. The average consumption throughout the twelve months was 1·87 units per car-mile, compared with 1·97 units in the previous year. In this connection, it must be remembered that the conditions at Halifax are unusual, owing to the hilly nature of the town. The publication of figures of this kind, however, cannot fail to be appreciated by other managers and by electrical engineers in particular.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 3s. Add 10 per cent. for abroad or for foreign books.)

Telephonology. By H. R. VAN DEVENTER. (London: McGraw-Hill Book Co.) Pp. xii. + 586. 17s. 6d. net.

This book is divided into 16 chapters, and contains 586 pages of closely printed matter and 682 illustrations. The matter is not very well arranged, descriptions of apparatus, systems, clearing of faults and instructions for makeshift apparatus being crowded into the same chapter. The illustrations are frequently too small and the diagrams involved. There is no description of the subject under the illustration (only a figure number), and this necessitates frequent reference to the text. There is a great mass of useful information, however, and many examples regarding what may be called general telephony; but the book does not deal fully with the later developments and does not deal with private branch exchanges, transmission or loaded lines. Chapter I. deals with theory. Then follows a chapter which is devoted to signalling equipment. This contains a good deal of really practical information. The author first deals with the action of polarised bells and magneto generators, explaining their theory very clearly. He then sets out the advantages of the bridging, as compared with the series, system when a number of instruments are joined on one line, and shows how the self-induction of the ringer coils, which in the latter system is a serious drawback, becomes an advantage in the bridging system. He also discusses the design of series and bridging ringer coils, and furnishes some excellent data in the form of graphic curves bearing on the winding of coils. The curves, are, however, all worked out to B. & S. gauge.

The author rightly criticises the usual method of rating generators—that is, in terms of the resistance through which they will ring a bell, without quoting also the resistance of the bell used. He then explains his own method, which also brings in a debateable point—for example, he states on p. 43 that a good bridging generator should ring a 1,600 bell when shunted with a resistance of 40 ohms through a resistance of 2,000 in series with the generator. This is hardly consistent with the author's previous statement, as he does not mention whether a commercial ring is intended or the faintest tinkle. The only really satisfactory method is to measure the current which will give a commercial ring on the particular bell used, and then adjust the shunt until the required current is given through the ringer. The figures given for the output of generators must be considerably in advance of English practice if correct, as the reviewer has yet to find a three-bar generator that will give an open circuit voltage of 65 to 90 and an output of 150 to 200 milliamperes at 750 revs. per min. The same remark applies to the four-bar; the figures given for the five-bar are rather nearer the mark.

A novel type of ringer is described on p. 37, termed the Schwarze bell, which should have many useful applications. On pp. 38 and 39 the author shows that a large number of magnets does not necessarily mean a more powerful generator; an instance is given to show that a four-magnet generator may be considerably more powerful than a five-magnet. Another point he emphasises is the importance of the air-gap between the pole-pieces and the armature being as small as possible. This statement should be qualified, as experience teaches that if the clearance is too fine, directly the slightest wear takes place in the bearings the armature knocks badly. Another point is that the closer the armature is to the pole-pieces the greater the demagnetising action upon the magnets, thus reducing the output of the generator.

Chapter III. is devoted to Talking Equipment—*i.e.*, receivers, transmitters and induction coils. On p. 50 the author negatives the idea that the receiver which will lift the heaviest weight is the best, an idea which dies very hard. Several illustrations of really well-designed receivers are given, together with a rough method of testing receivers. On pp. 57 and 58 is described a method of making a revolution counter from a cheap alarm clock, of which novelty is the sole recommendation. He then deals with transmitters, all save one being of the solid back variety, and gives excellent illustrations of some of the latest American productions.

On pp. 97, 98 and 99 (Chapter IV.) a description is given of the different types of lightning arresters and their action. Chapter V. is devoted to magneto switchboards, starting with a description of the origin of the simplest switchboard circuit, followed by different types of indicators both manually and automatically restored. Some of the types shown seem almost super-refined, but serve to illustrate the ingenuity which has been expended upon this type of apparatus. A novel type of combined jack and indicator is illustrated, which also automatically rings the wanted subscriber when the plug is pushed home. A new local bell circuit is shown on p. 118, and has many advantages.

Chapter VI. deals with selective and lock-out systems. This chapter is especially interesting because although most of the systems shown will never be used in England, it illustrates to what a high standard party line apparatus has attained in America, as exemplified by the descriptions of the Leich, Baird and Homer Roberts systems. Explicit instructions are given to overcome any troubles which would be likely to occur in installing the different systems.

Chapter VII. is devoted to batteries. An ingenious and practical method is described on p. 215 for testing the life of batteries under as nearly as possible actual working conditions. Some very practical hints are given on the connecting up and general care of batteries. The second portion of the chapter treats of accumulators.

Chapter VIII. describes the testing of telephone parts, and is most practical. On p. 250, in describing the action of the tuning fork vibrator, we note the following: "This rise of current in the working coil R1 causes a rise in voltage at its terminals. This charges the condenser C1 to flow out." This reasoning does not seem quite clear. The method described of testing receivers is not as good as others in use. A useful test for obtaining the external characteristic of a repeating coil is given, and the method mentioned of testing magneto generators is a practical one. A rather vague description is given of the secohmmeter, and a standard of self-induction as used for the measurement of self-induction. No reference is made to the latest methods of testing apparatus at telephonic frequencies.

Digitized by Google

Fault localisation is the subject matter of Chapter IX. One noticeable feature is that the plug blocks in nearly all the American types of instruments are made from circular rod, a point which must enter very largely into the cost of such apparatus, and as there are no drawbacks attached to this method, except perhaps its appearance, it seems rather remarkable the practice has never been adopted in this country.

Chapter X. is devoted to measuring instruments and their uses, and is especially interesting as demonstrating the possibility of making any measurements in telephony (direct current) with the aid of an ammeter, voltmeter, milliammeter and a millivoltmeter. The latter part of this chapter may appeal to the amateur electrician, as full working instructions are given for making a galvanometer, ammeter and ohmmeter.

Chapter XI. includes some useful information on p. 350 in connection with the W.E. instrument circuit, and the coil used in connection therewith. There is also a good description of the theory of the W.E. circuit. But no reference is made in this chapter to the extended use which is being made of the electromagnetic receiver.

Harmonic party line systems are dealt with in Chapter XII. In the instructions great pains are taken to prevent any damage being done to their products by lack of skilled attention. Every risk down to the smallest detail is treated with the greatest respect, no knowledge at all being assumed on the part of the user. We note a typographical error on p. 438 under the heading, " How Worn Cells can be Detected," the word *west* being used instead of *wet*.

Chapter XIII. deals with line and cable construction, protection, &c. Some useful data in connection with cables are given on pp. 498 and 499, and the accuracy of Sir William Preece's K.R. law is reaffirmed. Chapter XIV. is devoted to the automatic telephone systems, and explains in a lucid manner the possibilities of the Automatic Electric Co.'s system. No mention is, however, made of the later developments with two wires without earth.

Chapter XV. deals with systems of simultaneous telegraphy and telephony. The information given is especially valuable from the fact that the matter of composite working is being taken up seriously in England by the various railway companies. One might suggest that a fuller explanation should be given of the operation of the phantom circuits. This chapter gives one the impression that the author is in a great hurry to get the book finished.

Chapter XVI. deals with wireless telephony, and is interesting as showing the probable lines along which the wireless telephone is likely to be developed, since it deals with a system which in 1909 had spoken a distance of 40 miles.

In conclusion, the work throughout is thoroughly practical, and should be welcomed as a valuable aid to telephone literature. One only regrets that private branch exchange boards are practically ignored. However, much valuable information is given which the reviewer has not seen in any previous text book.

Theorie der Krafteplane. By H. E. Timerding. (Leipzig: B. G. Teubner.) Pp. vi. + 99. M.2·60.

Since Rankine published in the " Philosophical Magazine " for 1864 his Paper on the " Principle of the Equilibrium of Polyhedral Frames " considerable advances and improvements in graphical methods of solving difficult statical problems have been made. These methods are in everyday use in practical engineering, and so a working knowledge of them is indispensable to the student. Unfortunately, some of the treatises on the subject fail to give satisfactory proofs of the fundamental theorems. Sometimes even obscure statements made in the original Papers are slavishly reproduced, whilst difficult steps in the proof are omitted. This leads students either to take the theorems for granted or to expend an excessive amount of time trying to clear up the difficulties. To all who have experienced these difficulties we can recommend this book. Within a hundred pages Mr. Timerding gives a helpful introduction to the theory of graphical statics. He very properly supposes that the reader wants a logical exposition of the subject, and that he possesses a good working knowledge of analytical statics.

A. R.

Die Vektoranalysis und Ihre Anwendung in der Theoretischen Physik. By Dr. W. v. Ignatowsky. Part II. (Leipzig: B. G. Teubner.) Pp. iv. + 123. M.2·60.

In the second part of this book Dr. Ignatowsky applies the mathematical results obtained in the first part. He shows that they can be usefully employed in proving the fundamental theorems in rigid dynamics, elastic solids, hydrodynamics, electrostatics and electrodynamics. The proofs given will satisfy even the most exacting of physicists. Both the Maxwell-Hertzian and the Lorentz forms of the general equations of electrodynamics are obtained, and it is instructive to note the differences in the results obtained on the wave and electron theory. Dr. Ignatowsky is to be congratulated on the thoroughness with which he has done his work.

A. R.

POWER ECONOMY IN ELECTRIC RAILWAY OPERATION.*

BY H. ST. CLAIR PUTNAM.

Summary.—The author describes some tests made on the Manhattan Elevated Division of the Interborough Rapid Transit Co., New York, in which a clock was used to record the amount of coasting in the operation of trains, the object being to obtain from the motormen a better manipulation of the trains and a greater economy in power consumption.

The clock used in these tests on the Manhattan Railway consists of a clock mechanism manufactured for factory and office use for recording the time of employés. To the balance wheel escapement a braking device has been added, as shown in Fig. 1, which is lifted free from the balance wheel by an electromagnet that is energised

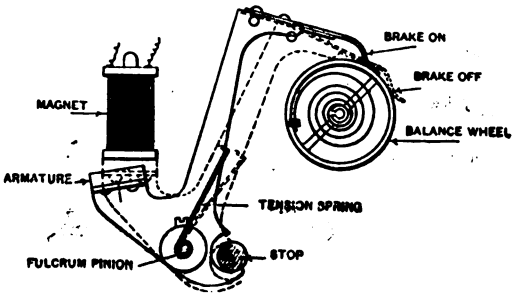

Fig. 1.—Details of Clock Mechanism.

only during the coasting of the train. This permits the clock to record the coasting time only. Each motorman is provided with an individual key which he inserts on taking charge of the train and again on leaving. The turning of this key records the motorman's number or initials and the time as shown by the clock mechanism; the difference in the time between the two records made by the key representing the total time of coasting during his run. The slip record is torn off by the motorman and handed to the proper official. This is checked up with his running time, and the motorman is rated according to the percentage that the coasting time is of the total time of his run, due allowance being made for variation from the schedule. His individual rating is based upon the average results of a week or month as may be selected. The electric circuits controlling the clock are interlocked with the master controller and the brake mechanism and arranged so that the coasting clock will start only after the two actions of turning the power on and then off. The connections used are shown in Fig. 2. The operation of the clock is stopped as soon as the air brakes are operated and the brake cylinder has started to move to the braking position. If, for any reason, after the brakes are applied, the air is released and additional coasting obtained before the train stops, this additional coasting is lost from the amount of coasting recorded unless power is again applied. This is not an important factor in normal operation as the actual amount of coasting of this character is small.

While the principles involved in the use of speed time curve calculations in electric operation are well understood, for the purpose of making clear the economies in power consumption that can be realised from the better operation of trains, which it is the object of this clock to encourage, the author discusses briefly the various factors entering into electric operation.

* Abstract of a Paper read before the American Institute of Electrical Engineers.

LIBRARY OF THE UNIVERSITY OF CALIFORNIA
Digitized by Google

Acceleration.—The rapid acceleration of trains, providing the schedule speed is unchanged, results in an important saving of power for two reasons, first, the maximum speed reached is less with a high acceleration, and, consequently, the train resistance is somewhat less; second, and of much greater importance, is the fact that with a high rate of acceleration, the speed at the start of braking is less than with a lower rate, and, consequently, the energy absorbed and lost in braking is less.

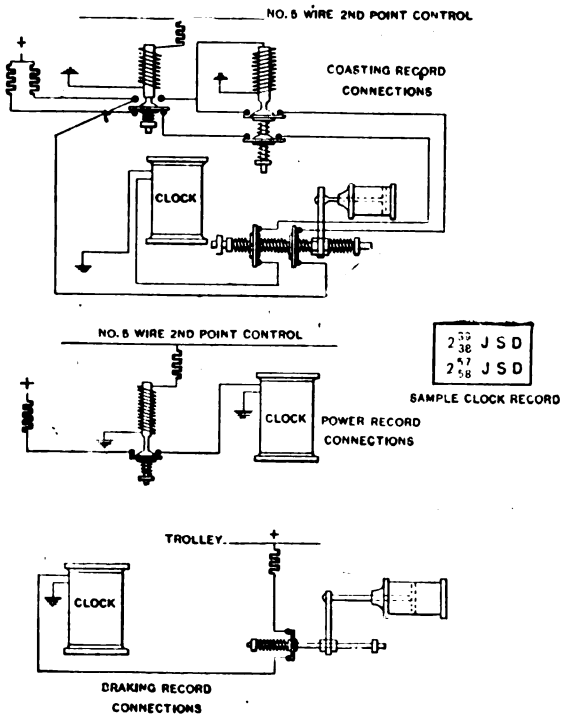

FIG. 2.—CLOCK CONNECTIONS.

The equipment provided naturally limits the permissible rate of acceleration, but within such limitations, a quick acceleration is one of the most feasible methods of saving power in such service as exists on the Manhattan Railway. In Fig. 3 is shown the percentage increase in coasting time resulting from the increase in the rate of acceleration from 0·9 mile per hour per second to 2 miles per hour per second, and the resulting decrease in power consumption, based upon an average run on the Second Avenue line. In the tests on the entire Manhattan system conducted on March 22, 1910, the acceleration of different motormen was found to vary from 0·9 miles per hour per second to 1·47 miles per hour per second. Providing other

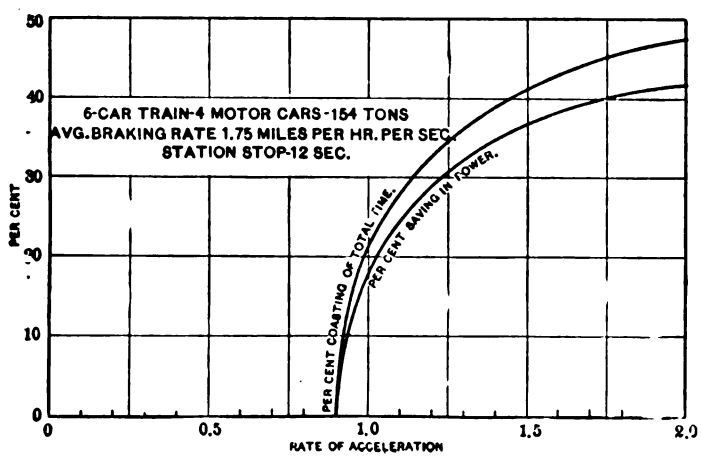

FIG. 3.—INFLUENCE OF ACCELERATION.

factors of train operation remain the same (that is, the braking, running time and time of stop) the increase in the rate of acceleration from 0·9 to 1·47 miles per hour per second will result in an increase in the coasting time of 40·5 per cent. of the total time, and a saving of 36 per cent. in energy consumption. A motorman on the Manhattan system on full runs will average about 600 car-miles per day, and the power used at the car with slower acceleration will approximate 2·82 kw.-hours per car-mile. As between these two motormen, therefore, providing the scheduled speed is maintained, the motorman who accelerated his train at an average rate of 0·9 mile per hour per second will waste during the day 610 kw.-hours at the car. With 80 per cent. efficiency to the power house, this becomes 762 kw.-hours. In practice the full saving of power resulting from better acceleration is not realised, owing usually to the better running time made by the good operator. This results frequently in his having to wait for the train ahead and by so doing, a large part of the saving in power which should follow his good operation is lost. The use of this clock should result, however, in a material increase in coasting time under such circumstances, with a resulting saving in power.

Series Running.—In Fig. 4, the effect of series running upon the percentage of coasting obtained and the resulting power consumption is shown. It will be noticed that an increase in the percentage of coasting obtained by reducing the amount of series running does not effect a corresponding saving in power. This is due to the fact that while the total time during which power is applied is increased and the time of coasting reduced by holding the controller in the full

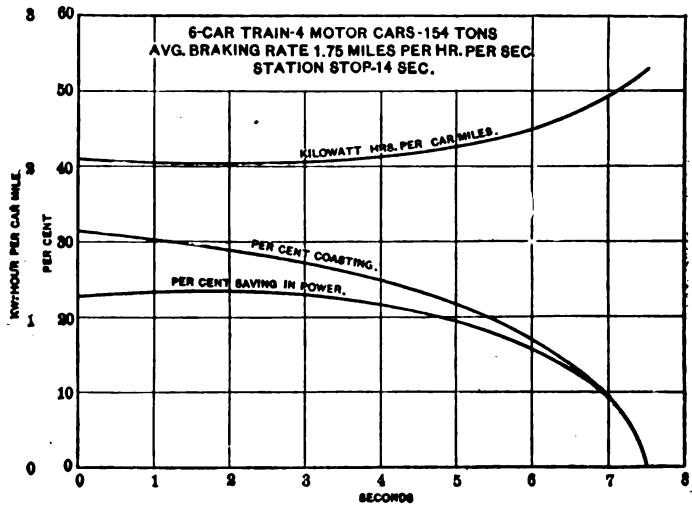

FIG. 4.—INFLUENCE OF SERIES RUNNING.

series position, say for four or five seconds, the actual power used remains practically the same because the additional power required on account of the longer time of power application is offset in large measure, if not entirely, by the saving in rheostat losses owing to the reduced time that the rheostat is in circuit in passing to full multiple. This is shown in Fig. 5, which has been used in calculating the results plotted in Fig. 4. A limited amount of series running, therefore, is not objectionable, and under certain conditions it is better to run in series for a short time than to pass to the multiple position,

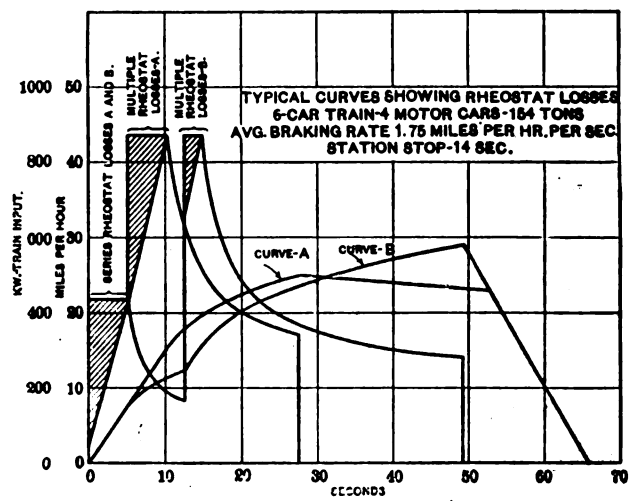

FIG. 5.—INFLUENCE OF SERIES RUNNING.

especially where power is cut off almost immediately after the multiple position is reached as under certain conditions in approaching a station. The decrease in coasting time resulting from a moderate amount of series running does not therefore necessarily represent an increase in power consumption, unless the series running has been excessive. In this respect the coasting clock will give misleading results; but as under normal conditions there is little occasion for running in series, except around curves, the error thus introduced into the record is not important.

Digitized by Google

Braking.—A high rate of braking results in a reduction in power consumption for reasons similar to those existing as to the rate of acceleration. It permits the power to be cut off at an earlier point, a longer time of coasting introduced, power otherwise wasted in the brakes to be recovered and the train brought to a quick stop. Perfection in braking is much more difficult of attainment than acceleration, as the train must be stopped at the station within a space limited to a few feet. Many motormen, therefore, operate on the side of safety and feel their way into stations, with a resulting material increase in the power used if schedules are maintained.

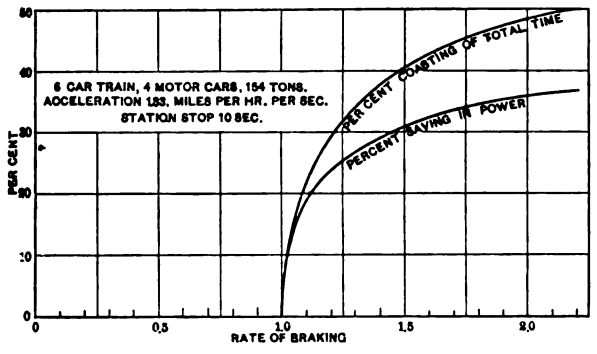

FIG. 6.—INFLUENCE OF BRAKING.

In Fig. 6 is shown the percentage of power saved on account of the increased percentage of coasting introduced by increasing the rate of braking from 1 mile to 2·25 miles per hour per second. These limits are frequently found in the operation of Manhattan trains.

Station Stops.—In Fig. 7 is shown the influence of the station stop. On the Second Avenue line, the average run is 0·335 mile and the maximum possible stop with the maintenance of the schedule, and with no coasting, is 16·2 seconds, assuming an average run as typical, which is substantially correct for the purposes of the present discussion.

Coasting.—The amount of coasting which a motorman can obtain and still maintain his schedule is obviously the result of the factors of operation above discussed. The ideal amount of coasting will result from the observance of all these factors. The theoretical coasting as shown on the typical curve is 27·5 per cent. of the total

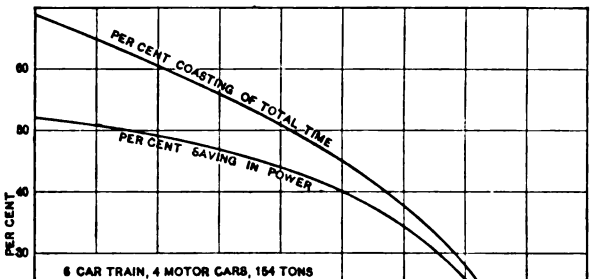

FIG. 7.—INFLUENCE OF STATION STOP.

time including stops. It has been shown in the above discussion that it is possible to obtain this amount of coasting and even to exceed it by changes in operation which are entirely within the range of practicability.

Power Consumption.—In Fig. 8 the calculated power required at the car, per car-mile, is plotted under different conditions as to acceleration, braking and station stops as above discussed, these factors being plotted in terms of the resulting percentage of coasting obtained.

Test Results.—The results of the tests of the coasting clock which have been conducted on the Second Avenue line are plotted in Fig. 9. All trains on the Second Avenue line were equipped with coasting clocks, and the power supplied to the section between 127th-street and Canal-street was metered by direct-current integrating watt-meters on the sub-station feeders. Corrections have been made for heaters and light, and the wattmeter readings corrected in accordance with frequent calibrations. On account of the corrections that have to be made for heaters, light, control and auxiliaries, the results obtained are necessarily approximate. Under these circumstances, therefore, the records are remarkably consistent and show graphically the material improvement in coasting which has resulted from the use of the coasting clock, and also the reduction in the power required for the operation of the cars.

These test results are plotted in further diagrams in the Paper, and are shown to agree very closely with the calculated curves given

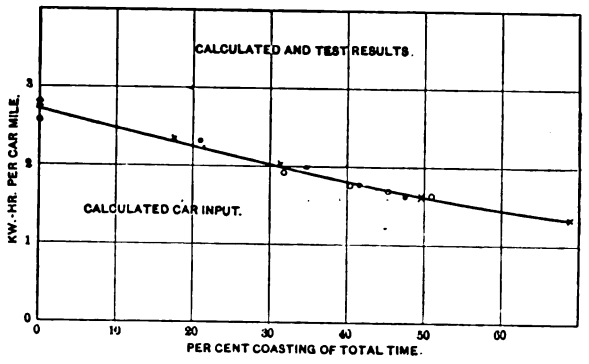

FIG. 8.—POWER REQUIRED PER CAR-MILE.

above. The important feature is that on the Second Avenue line the increase in the time of coasting from 10 per cent., as it was prior to the installation of the clocks, to 38 per cent. following such installation resulted in a saving of 25 per cent. in the power required for traction.

The author gives statistics and "running charts" of a large number of tests carried out on various lines of the Company. These tests bring out strongly that any system of rewards based upon coasting time should include a penalty for overrunning the scheduled time.

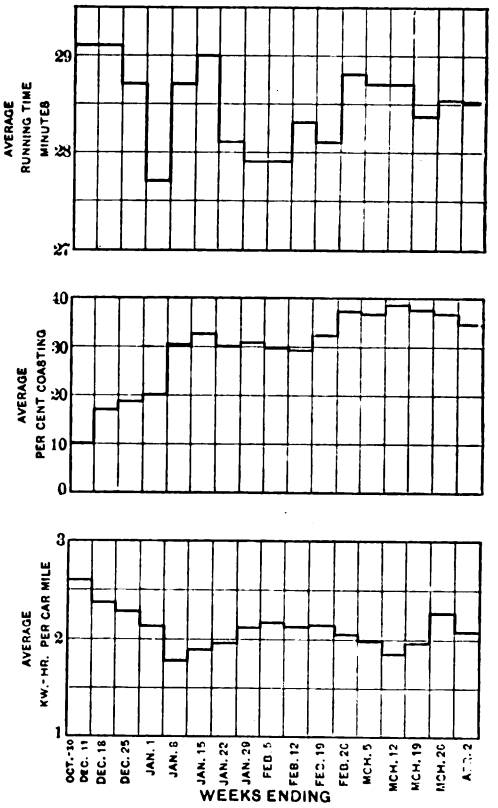

FIG. 9.—COASTING CLOCK TESTS ON SECOND AVENUE LINE, 127TH STREET TO CANAL-STREET, OCTOBER 30 TO DECEMBER 11, BEFORE CLOCK INSTALLATION; DECEMBER 18 TO APRIL 2, AFTER CLOCK INSTALLATION.

The various factors that enter into the operation of the train have been analysed with a view to determine which is the preferable element to measure. The choice practically narrows down to the measurement of either the power input by wattmeter or time of application by means of a clock arrangement, or the measurement

Digitized by Google

of the time of coasting. The author thinks it has been made clear that whatever good results are obtained from the better operation of the train by the motormen can only result in the saving in power through the increase in the coasting time. Coasting is the recovery of power already used, and hence is the key to the problem. The coasting clock, therefore, gives a direct measure of the power recovered by the motormen, and as this recovery can also only be made by cutting off the power application sooner, it is believed that it is the most effective element in train operation to measure. At the same time it concentrates the motorman's attention on that element of operation which is the direct reason for the saving in power which results from changes in the methods employed as to the other factors of operation.

THE TEMPERATURE COEFFICIENT OF RESISTANCE OF COPPER.*

BY J. H. DELLINGER.

The values in common use for the temperature coefficient of copper vary from $a_0 = 0{\cdot}00398$ to 0·00445, or $a_{20} = 0{\cdot}00369$ to 0·00409 (a_0 and a_{20} are defined respectively by the equations: $R_t = R_0 (1 + a_0 t)$, and $R_t = R_{20} (1 + a_{20} [t-20])$, in which t = any temperature Centigrade, and R_0, R_{20}, R_t = resistance respectively at 0°C., at 20°C. and at t°C.). The differences in these various values assumed as standard may be considered to be due either to errors of the measurements made in establishing them or to differences in the temperature coefficients of different samples of copper. In either case, accurate results cannot be expected when one of these values is taken as fixed and used for all samples. That this fact is not recognised is shown by the common practice of assuming that the temperature coefficient is the same for different samples of copper, while the conductivity is usually measured. It was accordingly considered of importance to determine whether the temperature coefficient of different samples does vary, and also to find whether there is any simple relation between the conductivity and the temperature coefficient.

This investigation has shown that there are variations of the temperature coefficient, and that to a fair accuracy the relation of conductivity to temperature coefficient is a simple proportionality. Thus, annealing is known to increase the conductivity of hard-drawn wire; it was found that annealing increases the temperature coefficient by an exactly proportionate amount. Samples varying in the amount of chemical impurities are known to vary in conductivity; it was found that the temperature coefficient was substantially proportional to the conductivity.

Samples were investigated from 14 of the most important copper refiners and wire manufacturers in the U.S.A., Germany, France and Austria. The range of conductivity of the samples covered thoroughly the range of the copper furnished to the electrical industry. The experimental work was carried out with wires, most of which were No. 12 B. & S. gauge about 120 cm. long. The resistivity and percentage conductivity were computed from measurements of the length, mass and resistance. The resistivity is given in "ohms per metre-gramme" by multiplying the resistance per metre by the mass per metre. The "per cent. conductivity" is calculated on the assumption that 100 per cent. conductivity corresponds to the arbitrary standard resistivity of 0·153022 ohm per metre-gramme at 20°C. The resistance measurements were made in a specially designed apparatus, by the Thomson bridge method. Temperatures were measured with a mercury-in-glass thermometer. The accuracy of the resulting conductivity values is estimated as within 0·03 per cent., and of the temperature coefficient values within 0·000004, or 0·1 per cent. To an accuracy of 0·2 per cent., the temperature coefficient was found to be linear between 10°C. and 100°C. The results of the measurements on the separate samples are given in a table in the Paper, the mean value of C for 37 samples being 0·003938, the greatest deviation from the mean being 0·000018.

The effect of bending and winding of wires was also investigated. Any distortion of an annealed wire is known to produce local hardening and increase of resistance. It was found that much the greater part of this increase was due to local changes of cross-section and not to the change of resistivity. This was shown by the fact that while the apparent conductivity decreased, the temperature coefficient changed practically not at all. This having been established for cases of bending and distortion more severe than those arising in ordinary practice, it may accordingly be assumed without serious error that the temperature coefficient of a copper wire is the same after winding on a machine or instrument as it was before. Accordingly, if a measurement has been made of either the conductivity or the temperature coefficient of the wire before winding, the temperature coefficient may safely be assumed to be known after winding, and may be used in the calculation of temperature rise.

The main result of this investigation may be expressed in the form of the following practical rule: The 20°C. temperature coefficient of a sample of copper is given by multiplying the number expressing the per cent. conductivity decimally by 0·00394. The rule can be put in a remarkably convenient form for reducing the results of conductivity measurements to a standard temperature, viz., the change of the resistivity per degree C. of a sample of copper is 0·000598 ohm per metre-gramme, or 0·00681 microhm per centimetre cube. The last two constants are independent both of the temperature of reference and of observation, and also independent of the sample of copper.

The foregoing results indicate that the measurement of conductivity may often be replaced by a measurement of the temperature coefficient. Four particular cases suggest themselves in which the measurement of temperature coefficient has considerable advantage over a conductivity measurement: (1) Odd shapes. Unless a uniform sample can be prepared, the determination of conductivity directly is hopeless. (2) Short samples, for which the difficulty of measurement of the dimensions and the possible uncertainty of the current distribution limit the applicability of conductivity measurement. (3) Wires that have been distorted or bent. As shown above, the apparent conductivity of a distorted wire is incorrect, while the temperature coefficient is not materially changed. (4) The estimation of chemical purity, of which the conductivity is a familiar criterion. Evidently the temperature coefficient is fully as reliable a criterion as the conductivity, and is more generally applicable, and is often an easier test to apply than either the conductivity or chemical determinations.

* Abstract, from the "Journal" of the Franklin Institute, of a Paper in the Bulletin of the Bureau of Standards.

CORRESPONDENCE.

THEORY OF THE QUADRANT ELECTROMETER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Recent correspondence in your columns has made it clear that the idea of electrostatic control, as an essential factor in the theory of the quadrant electrometer, by no means meets with the general acceptance which its utility undoubtedly merits. In view of this, I should be glad to have the opportunity of explaining, in the briefest possible manner, how the very elementary and, within its limits, quite legitimate device of resolving the total electrostatic couple acting on an electrometer needle into (1) a deflecting component independent of the deflection θ, and (2) a controlling component proportional to θ, enables a general electrometer formula to be written down, if not directly, at any rate with the utmost ease.

Let V_1 denote the potential difference between the needle and one pair of quadrants, V_2 the potential difference between the needle and the other pair of quadrants, and V_3 the potential difference between the two pairs of quadrants. Then the behaviour of an electrometer whose needle is totally enclosed by the quadrants, or effectively shielded by them, is determined solely by these quantities, or rather, since $V_3 = V_1 - V_2$, by any two of them, say, V_1 and V_2. Moreover, both the deflecting and the controlling components of the electrostatic couple must be homogeneous quadratic functions of these variables.

If the electrometer is unsymmetrical, little of importance beyond these bare facts can be deduced, either on the present theory or on any other, except by invoking the aid of experiment to discover exactly what terms should enter into the various expressions concerned. But if the electrometer is symmetrical, and is so adjusted as always to give equal deflections in opposite directions when V_1 and V_2 are interchanged, then it is possible to lay down the following two further conditions which must be complied with by the deflecting and controlling couples respectively, these conditions being a direct consequence of the fact that an electrometer, adjusted as described, possesses double symmetry in the sense that it is symmetrical with respect to both the deflecting and the controlling forces.

In the first place, the deflecting couple must obviously remain unaltered in magnitude, but must reverse its sign, when

Digitized by Google

V_1 and V_2 are interchanged. This couple must, therefore, be represented by $aV_3(V_1+V_2)$, where a is an instrumental constant.

Secondly, the coefficient of the total controlling couple—that is to say, the factor by which θ has to be multiplied in order to obtain the total controlling couple—must remain unaltered, both in magnitude and in sign, when V_1 and V_2 are interchanged. Now the coefficient of the total controlling couple is made up of two parts. One of these, k, relates to the mechanical control and is necessarily independent of V_1 and V_2. The other relates to the electrostatic control, and, being a function of V_1 and V_2, must fulfil the above-stated conditions; it must therefore be represented by the expression $bV_3^2+cV_1V_2$, where b and c are instrumental constants. The total controlling couple is thus $(k+bV_3^2+cV_1V_2)\theta$, and by equating this to the deflecting couple, as just determined, we get

$$\theta=\frac{aV_3(V_1+V_2)}{k+bV_3^2+cV_1V_2}.$$

This is the shape which the formula for a symmetrical electrometer with an efficiently shielded needle, and adjusted as already described, is bound in general to take. By making use of the relation $V_3=V_1-V_2$ we can, of course, transform it in various ways to suit individual tastes; we can, for example, show that, as a particular case, it includes the formula given in my letter of August 26th. As it stands, however, it is the working formula of the symmetrical electrometer in its most general form; and to anyone who cares to acquire even a slight familiarity with the point of view here advocated, the result can hardly fail to be almost obvious. There is no difficulty in devising methods of determining the several constants which enter into this formula; but anyone specially interested in the matter will naturally consult the published accounts of work done at the Reichsanstalt on this subject during the past few years.—I am, &c.,

Manchester University, Sept. 19. ROBERT BEATTIE.

TARIFFS AND METAL FILAMENT LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With regard to your note in to-day's issue of THE ELECTRICIAN, I see that you incline to the view that if the "Telephone" form of tariff is to be modified, it would be better to omit the fixed annual charge, and merely to charge a predetermined number of units per quarter at a higher price, say 6d. per unit, all units in excess being at 1d.

The difficulty in this case would be, as we found in the maximum demand system of 8d. and 1d., that the consumer does not know when he is getting off the 6d. units and on to the 1d. ones. Practically no consumers ever read their meters, although we endeavour to get them to do so. When the consumer has paid his annual or quarterly charge under the "Telephone" system, he then knows that the whole of his units supplied are at 1d. each.

You are perfectly correct in saying that the fixed number of units can be easily determined, but the question of tariff must be looked at from the consumer's point of view, and the fact remains that *he* does not know whether he is using at a given time 6d. or 1d. units.—I am, &c.,

St. Marylebone, Sept. 23. A. HUGH SEABROOK.

[Undoubtedly these questions must be looked at from the consumer's point of view, and probably neglect of this precaution falsified the hopes of those who originally favoured the maximum demand system. We do not think, however, that the consumer would have any difficulty in appreciating a tariff in which a predetermined number of units were charged at a higher price. If, for example, the first 30 units in a quarter were charged at 6d., the consumer would know that he would have to pay 15s. before getting on to the penny rate. It might, of course, be a stipulation that the consumer would have to pay for this number of units in any case as a minimum, though we doubt if this would be the wisest course to adopt. It will be seen that the payment of a predetermined number of units in this way is much the same as the "telephone tariff," only that the consumer pays when he has had the units, instead of paying to a large extent in advance.—ED. *E.*]

MOTOR CAR LIGHTING.

Where a supply of electricity can be obtained the adoption of electric lighting offers so many advantages over the use of other illuminants that it is not surprising that efforts have been made to bring these advantages within the reach of all vehicles. In the case of automobiles, several systems have been introduced in which a dynamo is employed; the most recent, and certainly one of the most interesting, is that of Messrs. C. A. Vandervell & Co., of Acton, London, W. Where a dynamo is used the difficulty, of course, is

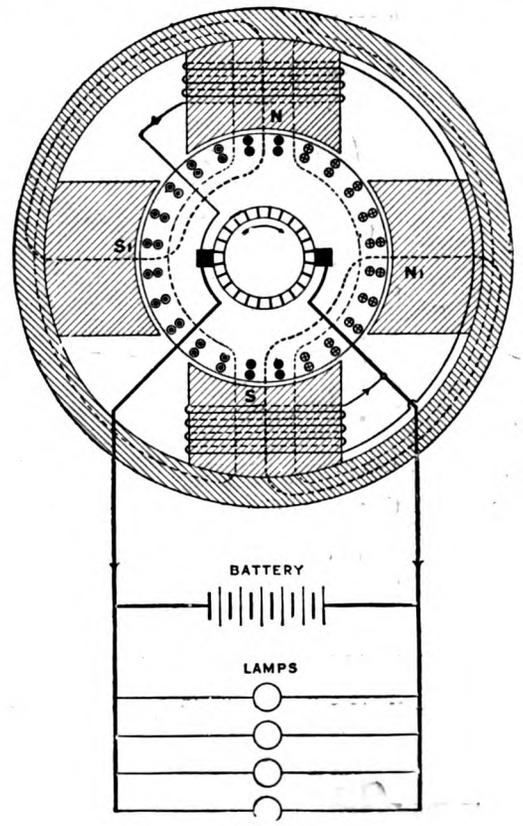

FIG. 1.

to obtain an approximately constant output at varying speeds, and resistances and cut-outs have usually largely figured in previous attempts at a solution of the problem.

The feature of the "C.A.V." dynamo car-lighting system of Messrs. Vandervell is undoubtedly its simplicity, the output of the generator being maintained constant by the magnetic reaction of the armature and field magnets. Two shunt-wound poles N, S, and two unwound poles N_1, S_1 are provided, as shown in Fig. 1. Commutation takes place under N, S, as indicated by the black dots for the conductors (the brushes being in a position at right angles to the conductors). The effect of this is to cause the armature to have a demagnetising

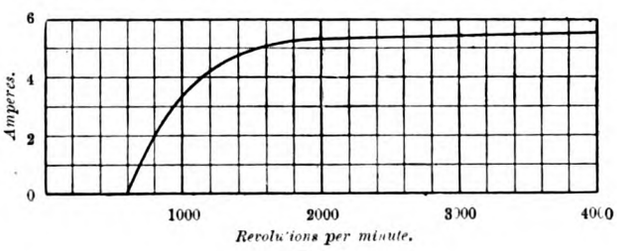

FIG. 2.

reaction on N, S, and thus the current does not rise above a certain value, and a constant current can be maintained at different speeds. At first sight it is difficult to see how satisfactory commutation can take place, but we gather that this is rendered possible by the redistribution of the flux between the wound and unwound poles as this demagnetisation comes into play. A typical output curve of one of these generators, showing the exceptional steadiness of the current over a very wide range of speed, is shown in Fig. 2.

Any standard winding can be adopted for the armature, but Messrs. Vandervell are using a patent winding in which the coils

Digitized by Google

cover an arc of 120 deg., instead of the usual 180 deg. in a two-pole machine.

Accumulators form an essential element in any car-lighting system, and thus the use of a dynamo of this kind means that a steady charging current is obtained over a wide range of speed. This, of course, favours the obtaining of better results, since a smaller battery can be carried and the plates have a more satisfactory life. It is also particularly interesting to notice that the principle of the "free wheel" has been adopted by Messrs. Vandervell for the armature (Fig. 3). This had made possible the elimination of cut-outs. Thus, when the driving engine slows down an excessive current is not taken from the accumulators (which would otherwise be the case if no cut-out were used), but the battery supplies about 1½ amperes to

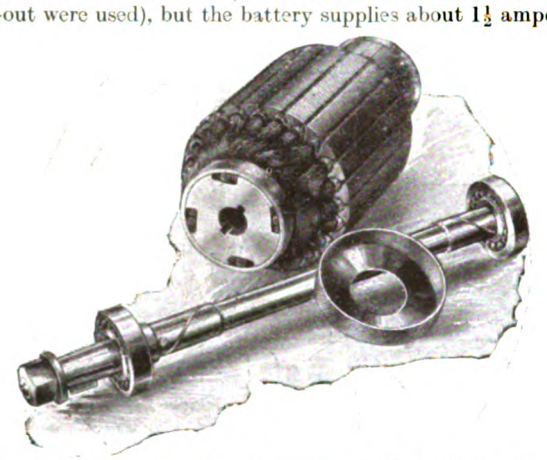

FIG. 3.—ARMATURE AND SPINDLE, SHOWING FREE WHEEL CLUTCH.

the dynamo, which then runs idly as a motor. It may also be mentioned that the capacity of the dynamo is less than that of the lamps, so that overcharging of the accumulators is unlikely. During the daytime when the dynamo is not supplying the car lights, its voltage rises as the battery becomes charged, the current at the same time decreasing. When desirable, current from the dynamo is cut off by the switch seen at the extreme left hand end of the row of switches in Fig. 4. The remaining switches control the car lights, for which metal filament lamps have been adopted of Edison & Swan manufacture.

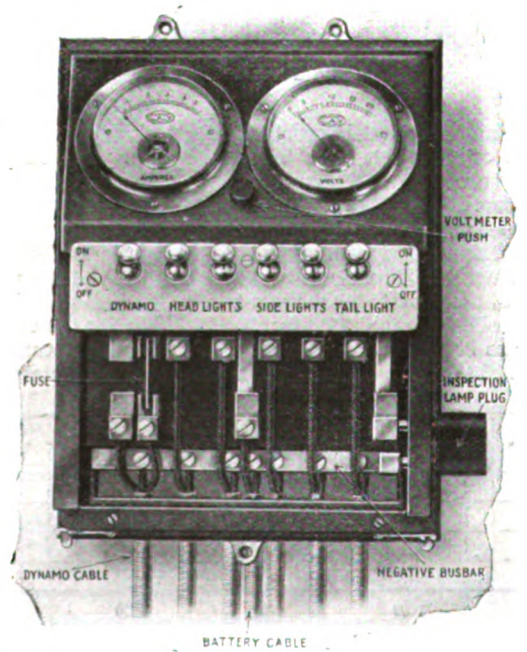

FIG. 4.—SWITCHBOARD, WITH FRONT OPEN SHOWING CONNECTIONS.

The dynamos are made to give a pressure of 6 or 12 volts, and a fixed output of 5 amperes, the generators of smaller output being intended for taxi-cabs. The output curve of such a dynamo is shown in Fig. 2 above, and it will be noticed that the generator begins to charge the battery at a speed of 600 revs. per min., and at all speeds above 1,800 revs. per min. it gives a practically constant output. This machine is intended to be geared so as to run at about 1½ to double the speed of the engine. Fig. 5 illustrates one of the dynamos ready for installation on a car.

In most cases it is proposed to fix the dynamo under the bonnet and to support it on a small bracket, in which case the dynamo may be belt or chain-driven from some revolving part of the engine, or it may be gear-driven or coupled direct.

The wiring of the car is by no means an unimportant detail, and particular attention has been paid to this by Messrs. Vandervell. In the "C.A.V." patent flexible armoured cable, the conductors, which are specially insulated, are protected by a spiral armouring, the latter

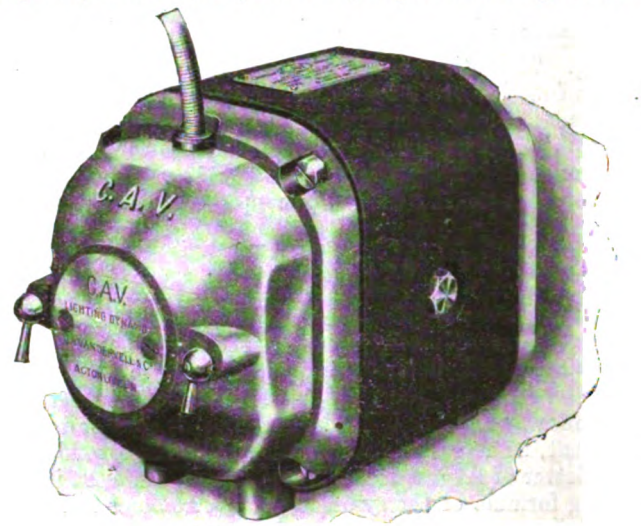

FIG. 5.—C.A.V. DYNAMO.

having no tendency to unwind even if cut. Special lamp-holders and lamps have also been designed, and, in fact, no detail likely to add to the efficient operation of the lighting equipment has been overlooked.

As the C.A.V. system of car-lighting appears to be well adapted for train lighting, it is not surprising to learn that developments in this connection are to be expected.

CONTROLLERS FOR ELECTRIC TRACTION.

As the use of any particular piece of apparatus is extended, so its design develops. This is particularly true of Messrs. Dick, Kerr & Co.'s tramway controllers, which have been in use since the very earliest days of electric traction, and have equally been receiving over that period improvements tending to make them more efficient than they were at first.

For instance, some years ago a metallic shield blow-out controller was introduced, while the use of higher speed, top covers and magnetic brakes have all caused the adoption of modifications in the general design of this equipment. The metallic shield blow-out is still retained in the latest form of Dick-Kerr controller, which we illustrate herewith, while further improvements that have been effected are set out in the following paragraphs.

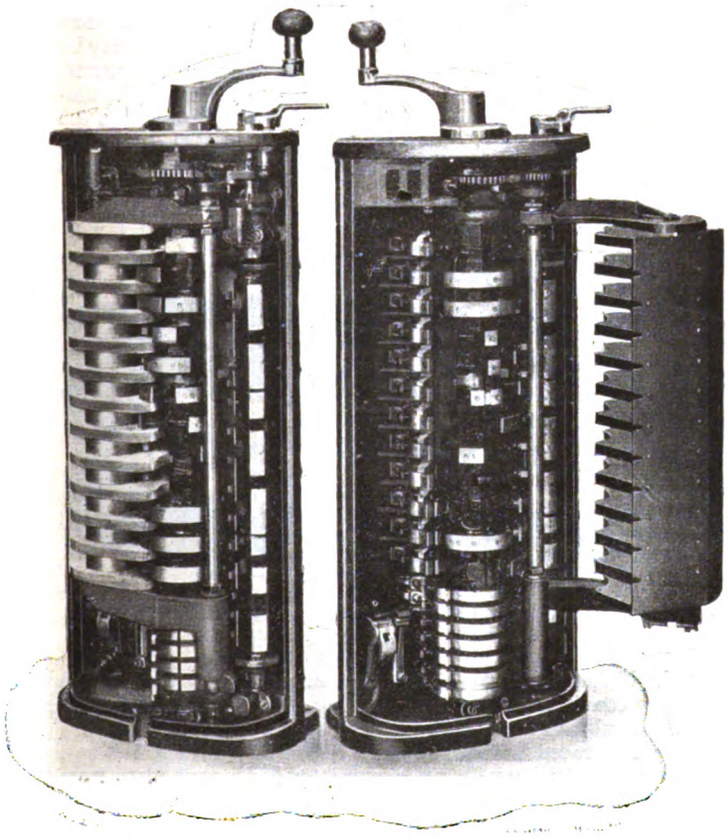
The main frame of the controller is, as usual, of cast iron of ample strength lined with suitable insulating material. The cover is of the enamelled sheet-iron type, but has been simplified by entirely dispensing with hinges and screws, while a simple but effective spring catch holds the cover firmly in position. The cover is lined with thick asbestos throughout, while mica sheets are provided at places opposite where arcs are broken.

The latest standard practice is followed as regards the construction of the cylinders, segments, fingers, as will be seen from the illustration. The contact fingers are provided with renewable copper tips, the adjusting screw of the contact fingers being automatically locked by a spring, thus obviating, it is claimed, the necessity of locking the screw by a lock nut or other device. The segments are made of the best hard drawn copper tubing, and all segment tips subject to burning are provided with short renewable tips. Wood has been entirely eliminated from the construction of the main power barrel, the shaft being of square section steel throughout, with mica insulation baked thereon. Round this insulation the segment castings are firmly clamped. The reversing cylinder is also strongly constructed, having a round steel shaft with a mica sleeve insulation, round which is fitted the wooden drum carrying the reversing contact plates.

The notching gear is, it is claimed, made as clear and as positive as is possible, consistent with absolute freedom of motion. There are 15 notches in all on the braking controllers, four for series work, four for parallel and seven on the brake side. The novel

Digitized by Google

feature of the braking type of controller is the combination of the brake and power cylinders on the same shaft. This eliminates the mechanical device which was previously necessary for throwing over a special brake cylinder when passing from the off position on to the brake notches; where magnetic braking is utilised to any great extent, this is, it is pointed out, a notable improvement, for it ensures the braking action being reliable and positive. A separate reversing cylinder is provided. This is operated in the usual manner by the reversing handle, and the arrangement employed by Messrs. Dick, Kerr of interlocking the reversing and power handles is also embodied in this design. By this means it is impossible to switch on the power until the reversing handle has been removed to the ahead or reverse position, while the reversing handles cannot be removed until the power handle is brought back to the off position. The reversing handle is only removable from the controller in the off position. An important modification has been introduced in regard to the power handle which is now non-removable from the controller. This is a practical point which Messrs. Dick, Kerr feel will be much appreciated by those responsible for controller maintenance, as it reduces maintenance cost, prevents the power handle from getting damaged or lost, while better and more positive operation of the controller is assured, and, consequently, there is a lower maintenance cost for the fingers and contacts generally.



STANDARD DICK-KERR TWO-MOTOR CONTROLLER ARRANGED FOR ELECTRIC BRAKING.

A point of practical utility is the arrangement of the motor cut-out switch. This consists of a knob projecting through the back of the controller at the top, which can only be operated by the reversing handle. Turning the knob either upward or downward through a quarter of a revolution cuts out either motor, or, in the four-motor controller, a pair of motors, the intermediate position leaving both or all motors connected. Thus a motorman can, in a few seconds, by means of his reversing handle, throw any motor or pair of motors in or out if he desires to test them; this saves any block in traffic, and also obviates the necessity of the motorman meddling with the controller in any other way. The cut-out switch is also interlocked with the reversing cylinder in such a way that it is impossible to cut out a motor except when the reversing switch is in the off position, and it is impossible to move the reversing switch except when the cut-out switch is in an operating position. It is impossible therefore for the motorman to make a mistake. In cutting out either motor a locking lever is raised, which prevents the power barrel from being moved beyond the last series position. Each motor, when running single, will therefore start up as usual on the first series notch of the controller.

NEW ELECTRICAL SHOWROOM IN HACKNEY.

It was a happy idea of the electrical powers at Hackney to open their new showroom at 306, Mare-street, on a Thursday afternoon. Thursday afternoon happens to be early closing day in Hackney, so that the attention of many of the matrons of the district, which would doubtless otherwise have been fixed on the goods in the drapers' windows, was concentrated on the electrical apparatus on view in Mare-street. So great was the crowd that gathered to see a

FIG. 1.—EXTERIOR VIEW OF THE NEW SHOWROOM OF THE HACKNEY ELECTRICITY SUPPLY DEPARTMENT AT 306, MARE-STREET.

laundress at work with an electric iron in one window, and two lady lampmakers testing Tantalum lamps for vacuum, voltage and mechanical defects in the other, that a sergeant and two members of the police force, not to mention a commissionaire, had to be retained to keep a way clear for those who wished to obtain further information about the electrical appliances from the attendants inside the showroom.

Some enterprise of this kind is undoubtedly needed in Hackney, for on our way down we noticed a sign which informed all travellers on the Great Eastern Railway that "Gas is Cheaper than Electricity for all Purposes." It is this sort of general inexactitude that Mr.

FIG. 2.—INTERIOR VIEW OF THE ELECTRICAL SHOWROOM AT HACKNEY.

Robinson has to fight against in Hackney, as electrical engineers have to elsewhere, and the opening of a showroom should be an excellent way of carrying on the campaign. We are pleased to see that great stress is being laid on the domesticity of electrical apparatus. Radiators and ovens of all types are on view, while on the occasion of our visit samples of food which had been cooked by electrical means were handed round for inspection. Seeing is believing in such cases, and many of the visitors were able to recognise through several

Digitized by Google

of their senses the benefits obtainable by the use of electrical cooking apparatus. There was no burning or smell.

The showroom is provided with a good stock of fittings and is well lighted. The general offices of the undertaking are now on the premises, which is a distinct step forward, for the benefits which can be derived by the removal of the directing staff from the generating station in a remote part of the borough to a situation in the main street are not small.

Hackney have powers to sell electrical fittings and to do wiring, but we understand Mr. Robinson proposes to allow this work as far as possible to pass through the hands of contractors, which is as it should be, in our opinion.

The accompanying illustrations, which have been kindly lent us by Messrs. Siemens Dynamo Works, give exterior and interior views of the new showroom.

TROTTER'S ACCELEROMETER AND GRADIENT MEASURER.

The problem of how best to measure under working conditions the acceleration of a moving vehicle has lately become of extreme importance, and many attempts have been made to solve it. Some of the instruments designed for the purpose have not erred on the side of simplicity, while others have been bulky or insensitive. An

FIG. 1.

apparatus which, however, it is claimed, overcomes all these difficulties has been designed by Mr. A. P. Trotter, and is now made by Messrs. Everett, Edgcumbe & Co. This instrument works on the "spirit level" principle. It possesses great sensitiveness, and is at the same time simple and compact enough to be carried in the pocket, while it does not easily get out of order.

The general appearance of the instrument is shown in the accompanying illustrations. The instrument, which can be calibrated to any convenient scale, though the most usual is feet per second per second, consists of an accurately shaped glass tube completely filled with a special liquid except for a small air bubble, bearing a definite relationship to the diameter of the tube. The bubble acts as an index and the instrument has only to be placed so that it is at zero when the carriage is at rest, and points in the direction in which it is desired to measure the acceleration. It will then indicate the true acceleration in this direction and take no account of that in any other. The instrument acts on the pendulum principle, the bubble being "left behind" as the vehicle starts, the amount it is "left behind"

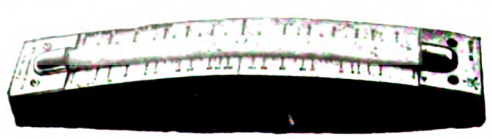


FIG. 2.

depending, of course, on the acceleration which is thus measured on the scale. The instrument is so constructed (*see* Fig. 2) that it can conveniently be placed on the window ledge of a tramcar, railway carriage, or motor car, and another pattern is made having a hinged bracket, which is particularly suitable for fixing to the dash board of a motor car, and is so arranged that when not required it can be swung out of the way (Fig. 1).

Should it ever be found that the acceleration or retardation to be measured exceeds the limits of the scale, the instrument may be set out of level to any required extent, so that, for example, when travelling along the flat the bubble stands at 4 ft. per second per second; this amount has then to be added to the actual reading when measuring accelerations, thereby increasing the available range to that extent. The instrument can also be successfully used for testing the retardation, while the stopping distance when testing brakes can easily be determined by a simple calculation.

PAUL'S DIRECT READING THERMO-ELECTRIC PYROMETERS.

In these days of scientific manufacture it is necessary that temperatures and pressures, volts and amperes, times and seasons should be known with great accuracy. Certainly not the least important of these data is temperature, and among the best instruments for the determination of high temperatures may certainly be included thermo-electric pyrometers.

Mr. R. W. Paul, of New Southgate, has recently designed a fresh series of these instruments which we describe below.

Such an instrument falls naturally into two parts, the indicator and the couple. The indicator in Paul's instruments is a low reading moving-coil voltmeter, the circular coil of which is pivoted at the centre of a spherical iron core, and carefully balanced so that its position is affected as little as possible by vibration or want of exact levelling. The pivot works in a finely polished jewel, from which it is completely lifted on depressing a plunger projecting through the top of the instrument, thus rendering the apparatus proof against rough handling in transit. The sensitivity attained allows the use of a moving coil of low resistance, in conjunction with a large resistance of negligible temperature co-efficient included in the instrument. Any error due to change of temperature of the indicator is thus reduced to a minimum, being less than 1 per cent. for a change of 20°C. The movement of the coil is controlled by a spring, and the index may be set to zero, should this be necessary, without opening the instrument, an external adjustment being provided for this purpose. The unipivot principle due to Mr. Paul is specially suitable for use when the small forces generated by thermo-couples have to be easily and accurately measured under workshop conditions, and it entirely, it is

FIG. 1.—VIEW OF PAUL'S WALL TYPE DIRECT READING THERMO-ELECTRIC PYROMETER.

claimed, eliminates the delicate suspensions previously used, which frequently caused trouble by accidental breakage, this necessitating the entire readjustment of the apparatus.

The indicators are made in two styles; the wall type (Fig. 1) is best suited for industrial work. It is supported by a wall plate from which it is readily removable. Notwithstanding its large scale it occupies but little space, which is a convenience when several instruments have to be placed side by side. The case is of cast iron and acts as a screen against external magnetic fields; it is of handsome design, stove enamelled, and relieved with brass fittings, and is perfectly dust-proof. The scale is marked in degrees Centigrade or Fahrenheit, and a second scale marked in millivolts renders it possible for an electrician to check the accuracy of the indicator separately. A magnifying device, with a movable index, may be fitted to this pattern, in combination with a swivel bracket (Fig. 2) which allows the operator to set the instrument to face in any desired direction and also enables him to see, from a distance of 30 ft. or 40 ft., whether the requisite temperature is being maintained.

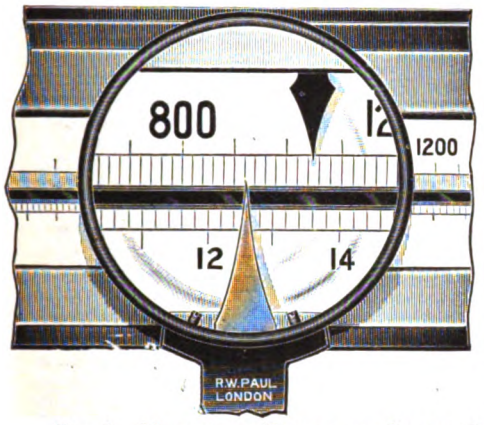
The portable type is for use where occasional tests of temperature have to be made in various situations. It has a horizontal scale, the working parts being mounted below an ebonite plate. The whole is entirely enclosed in a strong teak case and is fitted with detachable lid and strap handle. Each of the standard type indicators has an internal resistance of 100 ohms, 90 ohms of which consists of "swamping" resistance.

Great care has, Mr. Paul informs us, been taken in the selection of suitable materials for the thermo-couples and in the design of efficient protecting tubes, in order to ensure maximum durability and constant readings. For the measurement of temperatures between 600°C. and 1,200°C. pure platinum is used in conjunction with a platinum-iridium alloy. The electrical properties of the actual

Digitized by Google

materials employed have been investigated by the National Physical Laboratory, and large batches have been made up in order to secure exact reproduction of the results. The junctions are welded electrically, and a supply of spare wire is coiled on bobbins in the cold junction boxes, so that the welded junctions may be readily renewed in case of deterioration or damage.

Protection of the couple is afforded by a renewable steel sheath attached to an iron collar on the cold junction box by means of set screws, so as to be readily removable; while a quartz tube protects the thermo-couple from the furnace gases. A wrapping of asbestos twine separates the quartz from the steel tube, and protects it from accidental shocks. A small inner tube insulates the two wires. The platinum and platinum-iridium wires are 0·02 in. diameter, and the internal resistance of all mounted thermo-couples is brought to a total of 5 ohms, which, in conjunction with the care taken to secure uniformity of material, renders them, it is claimed, electrically interchangeable. In all mountings the external steel sheath, which is easily removed even by an unskilled man, is employed as a safeguard against accidental blows.



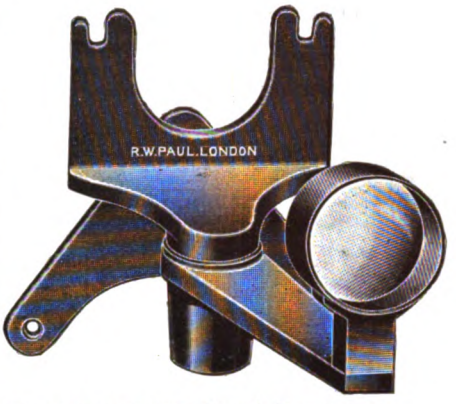


FIG. 2.—MAGNIFYING DEVICE AND SWIVEL BRACKET FOR USE WITH PAUL'S PYROMETER.

Since the readings of the indicator depend on the difference in temperature between the hot and cold junctions, it is obvious that the latter should not be exposed to high temperatures, either by radiation from the furnace or otherwise. The length of the couple, therefore, must be so chosen that the cold junction box may be at a proper distance, say, 18 in., from the wall of the furnace. Since the apparatus is standardised on the assumption that the temperature of the cold junction will be 20°C., it is necessary, when the greatest possible accuracy is required, to add the cold junction temperature, minus 20, to the reading on the scale. A thermometer may be used to ascertain this temperature, or a supplementary water-cooled junction may be adopted when it is not possible to cut down the temperature of the cold junction box within reasonable limits.

The standard form of cold junction box is provided with two holes into which corresponding plugs fixed to the supplementary water-cooled junction may be inserted. By using this attachment, a secondary couple is placed in series with, and in opposition to, the thermo-couple proper. This junction is immersed in water at a known temperature, preferably 20°C., contained in the body of the attachment, and this water may be easily renewed from time to time as it becomes heated. The further ends of the secondary couple reach the points in the cold junction box at which the main couple is connected. The attachment can also be provided with tubes for connecting to the water supply in order that a constant stream of water may be maintained.

ELECTRIC MOTOR SYRENS.

In some parts of the country, where factories abound, the steam hooter has long been in use for signalling the times of starting and stopping work, meal-hours, fire alarms, and for other similar uses. It also provides a convenient means by which the inhabitants of the district may set their clocks.

As the steam drive is more or less quickly vacating our factories in favour of the electric motor, so we may expect the place of the steam hooter to be occupied by the electric syren—an apparatus quite as capable of doing the work. Messrs. Siemens Bros. & Co. have supplied this want, and in the accompanying illustrations are shown the apparatus they have designed for the purpose.

Fig. 1 shows a small motor syren for signalling purposes. It may be used whenever it is necessary to give a specially loud and penetrating signal, or where a characteristic sound is desired. It may also be fitted with a device for giving sharply defined signals. This device consists essentially of an electromagnet with a protecting case mounted on the top of the syren; the armature of the electromagnet is connected with a disc which, in its normal position, closes the air inlet of the syren. Since the driving motor of the syren is connected in series with this electromagnet the armature becomes attracted immediately the motor is switched on, causing the disc to be withdrawn from the air inlet of the syren. As soon as the motor is cut off the disc is restored to its normal position by a spring, whereupon the syren immediately ceases to sound. By switching in the syren for longer or shorter periods, sounds of any desired length may be produced.

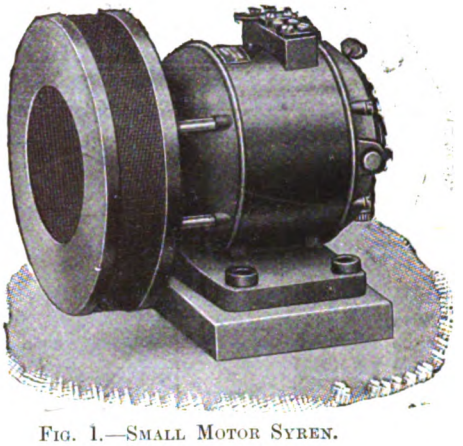

FIG. 1.—SMALL MOTOR SYREN.

Fig. 2 shows a larger type of syren, which is mounted on a round cast-iron base. This is fitted with a strong galvanised iron weather-proof case (Fig. 3) which allows the apparatus to be fitted out-of-doors. Another type of signalling device can be used in connection with this instrument. Behind the bearing covers of the syren are situated discs with radial slots, which, by being opened and closed, cause or prevent, respectively, a suction of air through the syren wheel. The discs are coupled with the armature of an electromagnet by means of a lever, the electromagnet being connected either in series or in parallel with the motor. When switching in the driving motor, the magnet is immediately excited and the air inlet opened by a movement of the discs. When the motor is cut off, current ceases to flow through the magnet and a spring moves the discs into their original position which causes the sound of the syren to cease instantaneously. This device permits of an intermittent signal of any desired length and avoids continuously running the motor and the consequent waste of energy.

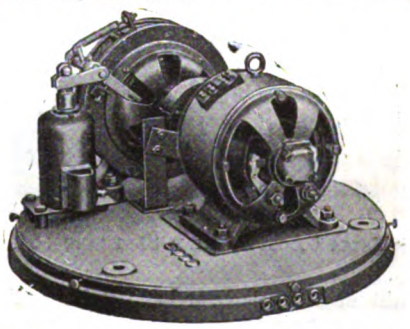

FIG. 2.—LARGE MOTOR SYREN WITH COVER REMOVED.

FIG. 3.—COVER FOR LARGE MOTOR SYREN.

THE "UNICA" ACCUMULATOR SEDIMENT PUMP.

One of the disadvantages attendant on the use of accumulators is the sediment that gathers at the bottom of the cells. Often the only efficient way to get rid of this is to take out the plates and strain the acid. To overcome this difficulty the "Unica" sediment pump, which we illustrate herewith, is now being supplied by Mr. S. Heilpern, of Manchester.

The "Unica" pump, which is sold at very moderate prices, will soon, it is claimed, pay for itself, as it allows the accumulator owner to keep his battery constantly clear of sediment, and therefore saves him the great inconvenience and heavy cost of washing out the cells. The pump is made in two sizes and is of guaranteed acid-proof materials. It is of simple and compact design, light in weight, easily portable and has no stuffing boxes or packings subject to wear and

"Unica" Accumulator Sediment Pump.

tear. Size I. will lift 5·28 gallons and size II. 2·64 gallons per minute of lead sediment, &c., from the bottom of the cells without requiring the plant to be shut down or the plates to be taken out of their receptacles.

The "Unica" pump may also be used for filling up the cells with acid or distilled water, while by its means acid can be pumped up to a great height, the pump being suitable for suction and delivery up to 32 ft.

THE PROPOSED ACTON TRANSFER.

At the meeting of the Council last week a report was received from the deputation appointed in June last to meet the directors of the Metropolitan Electric Supply Co., with a view of arranging the best terms possible for taking over the electricity undertaking. The deputation recommended the Council to accept certain terms, and that the common seal of the Council be affixed thereto, for the purpose of submitting the same to the company. The heads of the proposed agreement were:—

Upon Parliamentary powers being obtained (at the expense of the company) the Council to transfer to the company the Acton electrical undertaking for 42 years upon the terms of the Company's Act of 1906, of the Electric Lighting Acts of 1882 and 1888, and of the heads of the agreement. On the execution of the agreement the company to deposit £2,500, which sum, when the bill receives Royal assent, to be paid to the Council as part consideration for the transfer of the undertaking, but if the bill fails to receive Royal assent, to be forthwith repaid to the company.

The consideration for the transfer by the Council to the company (in addition to that in par. 2) shall be:—

(*a*) A covenant by the company to pay to the Council from time to time such sums as will be necessary to enable the Council to pay the annual interest and sinking fund charges on the loans contracted for their electrical undertaking, subject to the provisions with regard to street lighting.

(*b*) A covenant by the company, in addition to paying to the Council £2,500, that in the event of the net receipts of the undertaking amounting in any year to a sum exceeding 10 per cent. of the total capital expenditure at the end of that year, the company to make a further payment to the Council of one-half of such excess until the total further payments so made shall reach £2,500. The term "net receipts" to be gross receipts, less the cost of energy at the rate of £5 per kilowatt of maximum load and ¼d. per unit, together with all local expenses incurred in carrying on the said undertaking.

(*c*) A covenant that the company will not charge consumers more than the present charges for an equivalent candle-power and for the same hours of using as charged by the Council during the six months preceding the date of the transfer, or (in the alternative) that the profits of the undertaking to be divided among the company shall not exceed 10 per cent. upon the paid-up capital of the undertaking, unless a larger dividend be at any time necessary to make up the deficiency of any previous dividend, which shall have fallen short of the said yearly rate.

(*d*) And if the clear profits of the undertaking in any year amount to a larger sum than is sufficient to pay 10 per cent. dividend, after making up the dividend of any previous year, the excess to be applied towards reduction of rates of district.-

With regard to capital expenditure incurred by the Council on street lighting, the company to pay the interest and sinking fund charges thereon only if and while the Council contract with the company to continue to use electricity for street lighting to at least the same extent as at present.

The transfer to provide that if the Council decides to exercise its power of repurchase it shall give to the company five years' notice in writing, and during the currency of any such notice if any additional capital is required for properly carrying on the undertaking such additional capital, if desired by the company, to be provided by the Council, the company repaying to the Council the interest and depreciation charges on same.

The company to continue to supply energy in bulk to the Council from Jan. 1, 1911, to June 30, 1911, or such further time as may be necessary for passing the bill, at present rates.

On the motion to accept the suggested terms an amendment was moved in favour of asking the deputation to endeavour to secure better terms, and after discussion this amendment was carried by 11 votes to 10. Four members were then added to the deputation, bringing the number up to 11.

LEGAL INTELLIGENCE.

Workmen's Compensation.

At the Birmingham County Court on Friday Judge Amphlett, K.C., resumed the hearing of the application by the British Thomson-Houston Co. for the review of a memorandum of agreement (filed November, 1909) for the payment of £1 a week to George Mackenzie, an electrician, of Handsworth. Further evidence was given to the effect that Mackenzie was unable to undertake any work which would cause him to be on his legs for any length of time. It would be surgically impossible for him to do the same work now as he did before the accident.

Judgment reserved.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

The Governing Body of the Northampton Polytechnic Institute invite applications for the post of laboratory demonstrator in the electrical engineering and applied physics department. Applicants should be qualified to take charge of heat, photometric and electrical engineering laboratories. Commencing salary £100 per annum. Particulars and forms of application (which should be returned by Oct. 10) from the principal, Dr. R. Mullineux Walmsley. See an advertisement.

The Committee of Visitors of the County Asylum, Rainhill, Lancs., require an electrical engineer to take charge, under the medical superintendent and the clerk of works, of the generating plant and wiring at the asylum. Salary £120 per annum, rising to £150, together with house, coal and light. Applications to the Medical Superintendent, County Asylum, Rainhill, near Liverpool. See an advertisement.

An assistant is wanted in the electrical test-room by the Cambridge Scientific Instrument Co. Ltd., Cambridge. See an advertisement.

An experienced draughtsman is required for c.c. dynamo and motor work. Applications to the Manager, Electric Construction Co., Bushbury Works, Wolverhampton. See an advertisement.

Cleveland & Durham Electric Power (Ltd.), Hinton's-buildings, Middlesbrough, require junior electrical engineers with technical

Digitized by Google

training. Commencing salary 10s. a week. Applications to Secretary. See advertisement.

Test-room assistants are required, used to calibrating m.c. and e.m. instruments. See an advertisement.

The following appointments on the staff of the Northampton Polytechnic Institute (Clerkenwell, London) have recently been made:—

Assistant lecturer and demonstrator in the mechanical engineering department, Mr. A. B. Morice, B.Sc. (Eng.). Mr. Morice was trained at Merchant Venturers' Technical College (now Bristol University), and served his apprenticeship with Ferranti Limited, Hollinwood, Lancs. Mr. J. S. Norton has been appointed drawing office assistant and assistant lecturer in the same department. Mr. Norton spent four years in Messrs. Vickers, Sons & Maxim's works as apprentice, and acted as assistant instructor to apprentices' drawing class. The senior assistant at the new generating station is Mr. Angus MacKenzie, who has had considerable experience at home and abroad with electrical and gas engine plants. And Mr. W. H. Bird, who has been appointed junior assistant, has been apprenticed with engineers' fitter, and has had central station experience. The second lecture assistant in the electrical engineering department is Mr. F. D. Edwards.

Mr. Arthur Hale has been appointed second demonstrator in chemistry at the Finsbury Technical College.

Mr. W. S. Templeton, M.A., B.Sc., A.M.I.E.E., has been appointed Principal of the Devonport Technical School, in succession to Dr. W. M. Varley, who was recently appointed to Swansea.

Mr. D. P. Roberts, chief electrical engineer, of London, Ontario, has been appointed provincial inspector of electrical energy in British Columbia.

Mr. George Nelson, B.Sc. (London, first class honours), A.R.C.S., late demonstrator in advanced physics in the Royal College of Science, has been appointed assistant lecturer and demonstrator in physics at the Technical College, Sunderland.

Mr. J. G. Potts, of the Bury (Lancs.) municipal electricity works staff, has been appointed electrical clerk of works at the new power station.

EDUCATIONAL NOTICES.

University of Edinburgh.—The next session opens on Oct. 4. In the engineering department of the University complete courses of instruction are provided in civil, mechanical and electrical engineering, qualifying for the degree of B.Sc. in Engineering, and extending over a period of three years. Particulars of entrance examination scholarships, fees, &c., can be obtained from the Matriculation Office of the University.

University of London, University College.—A course of lectures on the "Design of Continuous Current and Alternating Current Machines" will be delivered by Mr. H. M. Hobart on Mondays at 5 p.m., beginning Oct. 10.

Armstrong College, Newcastle-on-Tyne.—The session commenced on Sept. 26. There are full courses of instruction in mechanical, marine, civil and electrical engineering, naval architecture, mining, metallurgy, agriculture, pure science, arts and letters. Particulars from the secretary, Mr. F. H. Pruen, M.A., Armstrong College, Newcastle-on-Tyne.

Finsbury Technical College.—The next session for evening classes (lectures and laboratory work in mechanical and electrical engineering, industrial and technical chemistry, &c.), begins on Monday, Oct. 3 at 6 p.m. A special course of six lectures on India Rubber will be given by Dr. P. Schidrowitz, F.C.S., on Wednesday evenings, from 7:30 to 8:30, commencing Oct. 12. The programme may be obtained at the College, Leonard-street, Finsbury, or at the head office of the City and Guilds of London Institute, Gresham-street, E.C.

Battersea Polytechnic (London, S.W.).—The day courses at this Polytechnic prepare for the B.Sc. degree (in engineering) of the University of London, and for the Polytechnic diploma in mechanical, electrical, civil and constructional engineering. The day courses commenced on 22nd inst. and the evening courses on 26th inst. Prospectuses from the Secretary.

Borough Polytechnic Institute.—The new session began on 26th inst. There is a four years' course of instruction in electrical engineering, and in electric wiring there is a three years' course. There are day and evening classes. Further particulars and detailed syllabus are given in the prospectus, which can be obtained from the Principal, Mr. C. T. Millis.

The prospectus gives particulars of the work carried on in the Institute. Amongst the alterations are the re-arrangement of the electric wiring courses, and there are some new classes in mechanical engineering. There has been an extension and development of the work in nearly all departments. Copies may be obtained from the Principal.

Northampton Polytechnic Institute (London).—Full day courses in the theory and practice of mechanical and electrical engineering and electro-chemistry will commence on Monday, Oct. 3.

The courses in mechanical engineering include specialisation in automobile and aeronautical engineering, and those in electrical engineering include specialisation in radio-telegraphy. The courses include periods spent in commercial workshops and extend over four years. They also prepare for the degree of B.Sc. in engineering at the University of London. There are full and part time courses in all branches of technical optics. Particulars as to fees, &c., can be obtained at the Institute, Clerkenwell, E.C., or on application to the principal, Dr. R. Mullineux Walmsley.

South-Western Polytechnic Institute (London, S.W.).—At this Institute a complete three years' course in electrical engineering is held during the day, and a four years' course in the evening. Courses of lectures and practical work are given in a number of subjects, including elementary, intermediate and advanced electrical engineering, electrical design, instruments and lamps, alternating and polyphase currents, wiring and fitting, and the calculus for engineers.

The evening classes commenced on 26th inst. and the day college opens on Oct. 3. The institute is provided with well-equipped electrical, mechanical and physical, chemical and metallurgical laboratories, and wood and metal workshops, &c. Particulars from the Secretary, Manresa-road, Chelsea, S.W.

Sir John Cass Technical Institute.—A course of evening lectures and practical work on "Fuel" will be given at this institute during the session 1910-11, including one on "Liquid, Gaseous and Solid Fuel," by Mr. J. S. Brame, on Monday evenings, 7-8 p.m., commencing Oct. 17; one on "Fuel Analysis" (and course of laboratory work), by Mr. C. O. Bannister, during the summer term on Monday evenings, 7-10 p.m., commencing April 24; and a course of laboratory work on "Gas Analysis" in the summer term, by Mr. Chas. A. Keane, D.Sc., Ph.D., F.I.C., on Wednesday evenings, 7-10 p.m., commencing April 26. The courses of instruction are arranged to meet the requirements of those engaged in chemical and engineering works, or who are concerned with the use of fuel for motive power. Detailed syllabuses of the courses may be obtained at the offices of the institute, Jewry-street, Aldgate, London, E.C., or by letter to the Principal.

Faraday House Special Lectures.—Mr. H. M. Hobart, B.Sc., M.I.C.E., has begun a special course of lectures on "Electric Railway Engineering" to the third year students at Faraday House. Mr. J. Rennie, M.I.E.E., of the Board of Trade Laboratory, is lecturing on "Electrical Measuring Instruments."

BRITISH NOTES.

Aldershot.—The mains are to be extended to Queen's-road.

Association of Chambers of Commerce.—At the autumnal conference last week it was resolved:—

That sec. 175 of the Companies Consolidation Act, 1908, should be so amended as to provide that when a winding-up order had been made the court should have power to direct a public examination of the directors or other officers of a company, or of any person who had taken any part in the promotion or formation of the company or had been a director or officer of the company.

A proposal for the establishment of tribunals of commerce was rejected.

A resolution was also adopted that the Factory and Workshops Act, 1901, should be amended so as to provide that in the case of orders given by factory inspectors to fence machinery or to provide exhaust or other ventilation there should, in case of difference of opinion between an inspector and an occupier, be an appeal to a tribunal composed of magistrates, assisted by expert assessors.

Barking.—The engineer and manager of the electricity department (Mr. Henley L. Howard) recently reported on the proposed extensions of the generating plant. Mr. Howard recommended the installation of a 600 H.P. Diesel engine coupled to a compound-wound direct-current generator with traction battery, three-phase motor generator and necessary switchboards, &c., and also the construction of a new engine room at the side of the existing engine room to house the new plant. The whole of the recommendations have been adopted by the Council.

Belfast Electrical Exhibition.—A sub-committee of the Tramways and Electricity committee, in conjunction with Mr. T. W. Bloxam, A.M.I.E.E., city electrical engineer, is making arrangements for holding an electrical exhibition in the Ulster Hall between Jan. 9 and 31, 1911.

Carlisle.—The Rural Council has consented to the proposed application of the Corporation for a provisional order to extend the area of supply.

Church Lighting.—Dr. Chalmers' Territorial Church, West Port, Edinburgh, which has recently been renovated, has been provided with an electric lighting installation. The wiring work, &c., was carried out by Messrs. Platt Bros., and the historic church is now brilliantly illuminated by metal filament lamps.

Digitized by Google

East Ham.—Barking Council has asked East Ham for suggestions as to a scheme of inter-running between the tramway systems of West Ham, East Ham and Barking.

The engineer and manager (Mr. W. C. Ullmann) is to bring up a report at the next meeting of the Electric Light and Tramway committee upon the question of providing additional condensing plant at the generating station.

Fifeshire.—The Road committee of the Kirkcaldy District committee have been informed by the Fife Electric Power Co. that they intend to erect an electric power cable from Lochgelly to Newton of Wemyss.

The Road Surveyor pointed out that the proposal of the company was to construct overhead lines of bare copper wire on wooden poles. The wires would pass over six highways within the district, and it was resolved to recommend the District Committee that the cables where they cross or pass alongside roads should be placed underground.

Fire.—A small fire occurred at the works of Messrs. Johnsan & Phillips, Charlton, on 26th inst., but only 6 tons of jute and a portion of a shed were destroyed. The prompt action of the firm's firemen prevented further damage.

Hereford.—The extensions to the Corn Exchange are to be wired.

Leicester.—The Electricity committee announce that they have decided not to appeal against the injunction granted against the Corporation in the proceedings instituted by the Attorney-General, at the instance of Mr. C. J. Utley, for an injunction to restrain them from carrying on the electric wiring and fittings department.

Leigh-on-Sea.—Southend Council have applied to the Board of Trade for an order to authorise them to supply current to the Leigh Cinematograph Hall. Leigh Council agree to the supply being given.

Llanelly.—Callender's Cable & Construction Co. has commenced the work of laying electric supply cables in this district.

Listowel (Ireland).—The Council is negotiating with electrical firms as to electricity supply.

L.C.C. Tramways.—Chelsea Council resolved on Wednesday to refuse its consent to the proposal of the London County Council to construct tramways in the borough to link up Kensington and Battersea.

Manchester.—A special meeting of the Corporation will be held on Wednesday to consider a bill to extend the time for completing certain authorised tramway lines, &c.

Manchester and Salford Amalgamation.—The subject of the amalgamation of the boroughs of Manchester and Salford is again being raised, and a petition, which has already been signed by a number of influential ratepayers (including Sir Wm. Mather, I. Frankenburg & Sons, the Broughton Copper Co., the Peel-Conner Telephone Works, &c.), is to be presented to Salford Corporation in favour of the proposal.

Mexborough.—An animated discussion arose at last week's meeting of the Council on a recommendation of the Highways committee to allow the Mexborough & Swinton Tramways Co. to run a motor char-a-banc service on the Wath and Denaby roads.

Mr. J. Rowan thought the application should be considered with the question of trackless trolley trams, in connection with which the Council had received a communication. The trackless trolley system would give an outlet for power from their own electricity undertaking.

Ultimately the recommendation was rejected by 5 votes to 4.

Municipal Wiring.—The following notifications of intention to support the bill of the Municipal Electrical Association to authorise municipal wiring, &c., have been received :—

Blackburn Corporation will consider the matter further when the bill is drafted; Hounslow Council will give moral support and reconsider the question of giving financial aid when the bill is drafted; and Manchester Corporation will give moral support and the question of giving financial aid has been deferred for the present.

National Electrical Manufacturers' Association.—The half-yearly general meeting of the Association will be held at the Midland Hotel, Manchester, at 2:30 p.m. Oct. 11. A committee meeting will be held at the same place on the same day at 11.30 a.m.

Obituary.—We regret to record the death of Mr. George Alexander Mason, which took place at Bahia Blanca (Argentina) on Sept. 23 from typhoid. Deceased, who was only 32 years of age, was in the employ of the Buenos Aires & Pacific Railway Co., having gone out to Bahia Blanca in January, 1909. His apprenticeship was served with Messrs. Crompton & Co., of Chelmsford, and he had also been with the B.T.-H. Co. (Rugby), the Brush Co. (Loughborough), and the Corporation electricity works, Grimsby. He served for 15 months with the Corps of Electrical Engineers in the South African war.

We also regret to record the death of Mr. Edward P. Martin, vice-chairman of Messrs. Guest, Keen & Nettlefolds, and a director of the South Wales Electrical Power Distribution Co. and other undertakings.

Newcastle-on-Tyne.—In consequence of the increasing demand for electrical energy for power at the works of Messrs. Hawthorn, Leslie & Co., at St. Peter's, some additions have recently been made to the plant in the local sub-station of the Newcastle-on-Tyne Electric Supply Co. from which these works are supplied.

The sub-station buildings have been extended, and now consist of three transformer chambers (29 ft. by 21 ft. by 14 ft. high). The sub-station is used for reducing the pressure from 5,500 volts, at which it is received from the generating station, to a pressure of 440 volts. The total capacity of the sub-station is now 2,000 H.P., there being three 700 H.P. transformers, oil cooled. The h.t. switchgear is of the Brown-Boveri "Grid" type, supplied by Messrs. Richardsons, Westgarth & Co. and consists of two feeder panels, each of 2,500 kw. rated capacity at 5,500 volts, and three transformer panels, each of 1,000 kw. rated capacity, while one extension panel is allowed for. The l.t. switchgear is of the Reyrolle ironclad type with three transformer panels, each of 1,000 kw. at a voltage of 440.

Olympia Engineering Exhibition.—After the close of this exhibition on Monday evening the exhibitors presented the organiser (Mr. F. W. Bridges) with a gold card case.

The chairman of the Council (Capt. H. Riall Sankey) made the presentation and Mr. Bridges acknowledged the gift in suitable terms.

At a meeting of the exhibitors on the same day a resolution was passed expressing entire satisfaction at the manner in which the whole of the arrangements have been carried out by Mr. F. W. Bridges, and at the successful result of the exhibition. It was agreed to support a similar exhibition, if held, in 1913.

Overhead Telephone Wires.—As Croydon Corporation failed in the recent arbitration proceedings in the dispute with the Postmaster-General in regard to overhead telephone wires in the borough, the Council have decided to pay the extra cost of placing the wires underground in certain cases where unsightly poles would be likely to depreciate property.

Personal.—Mr. A. S. E. Ackermann, B.Sc., A.M.I.C.E., has returned to London after an absence of 10 weeks in the United States, where he has been to test and report upon a new engine and to visit some of the latest engineering works.

Presentations.—Hanley Electricity staff have presented a case of Loewe pipes and a copy of Dr. J. W. Mellor's "Higher Mathematics" to Mr. C. H. Yeaman, on his appointment as chief electrical engineer of the new County Borough of Stoke-on-Trent.

Bournemouth Tramways staff have presented a cheque to Mr. A. H. Bowles on his marriage.

Rotherham.—On Tuesday the Council decided to promote a bill giving power to provide and run rail-less cars in a number of districts; to run motor omnibuses in the borough, and to extend the Wellgate tramways, and also additional powers relating to electricity supply, &c.

Scarborough.—The local tramways company notify that they will cease to run the trams during the winter months, commencing Oct. 15.

Surbiton.—The Board of Trade have appointed Dr. Alex. Russell, M.A., M.I.E.E., principal of the Electrical, Standardizing, Testing and Training Institution, Faraday House, to be an electric inspector under the Surbiton Electric Lighting Order.

Village Lighting.—The public electric lighting of the streets of Ainsworth (Lancs.) was inaugurated on Monday, when Mr. Hy. Whitehead, chairman of the Parish Council, formally switched on the current. The sub-station is located at the Ainsworth Cotton Co.'s mill.

Watford.—A discussion took place at the last meeting of the Council upon a proposal to oppose the Herts County Council's bill for powers to instal the rail-less traction system through Watford. Ultimately it was decided to proceed to next business. The Metropolitan Electric Tramways (Ltd.) are bearing the whole of the expense of sending a deputation from the Council to Berlin and Vienna to see the rail-less system working in those cities.

West Ham.—12 additional cars of the bogie type are to be purchased by tender, and application is to be made to the Board of Trade for sanction to a loan of £11,000.

Application was made during the vacation to the L.G. Board for a loan of £7,946 for motors and £6,027 for a turbo-alternator, and sanction has been received for the raising of these amounts.

The Electricity committee report that, in connection with the accounts of the undertaking to March, 1910, they have decided to write down the value of certain stores by £2,800, and have agreed to the appropriation of part of the reserve fund to meet the deficiency. The committee also report that on a communication from the Borough Treasurer they have resolved to ask the Fianace committee to include £18,000 in the next half-year's estimate, being the estimated deficiency on the electricity undertaking at March 31, 1911.

The borough electrical engineer (Mr. H. H. Couzens) has reported that with regard to the contract for the new turbo-alternator, the contractors (the British Westinghouse Co.) had agreed to replace the existing 3,000 kw. turbine with one of the Rateau type, the guarantees being the same as for the new set provisionally ordered. After investigation, Mr. Couzens

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough or constant use, price 8s. 6d. post free. A complete Index is included.

was not satisfied that the contractors could adhere to the original delivery given for December, and as some of the new supply contracts would not commence until after the winter's load, the machine would not be required until about July of next year. He, therefore, recommended that the existing turbine be replaced with the Rateau machine as soon as possible, a course which the committee agreed to.

Wigan.—Sanction has been received by the Council to a loan of £30,083 for extensions of the electricity undertaking.

Wireless Telegraph Notes.—An announcement has been made that the Marconi Co. have received a message from Mr. Marconi on board the ss. "Prinsipessa Mafalda," that he has successfully obtained wireless messages from Clifden (Ireland) and Glace Bay (Canada) on board the ship for distances up to 3,500 miles in broad daylight. A kite was employed to support the aerial wire on board the ship. The distance compares with the highest former record of 1,750 miles.

The London correspondent of the Sheffield "Daily Telegraph" discussed in the issue for Sept. 23 the subject of wireless steering of war ships.

Out of 98 days passed at sea by the "Otranto" (Orient line), the vessel was 81 days in wireless communication either with shore stations or with other vessels. The "Otranto" is fitted with the Marconi apparatus, and during a journey out from London was in continuous contact with Poldhu for a distance of 1,600 miles.

The ss. "Nonsuch," of what is known as the tramp class of steamer, is fitted with wireless telegraphic apparatus on the British Radio-telegraph Co.'s system, and reports that she was in communication with the North Foreland up to 15 miles south of Cape de Gata, the south-east point of Spain, and 940 miles distant from the Foreland.

The chief point of interest in wireless telegraph work at the present time is the establishment of effective communication with submarine vessels, both from the shore and from more or less adjacent war ships. Important experiments (following those in Torbay) are being conducted at Portsmouth and Devonport. It is reported that continued success follows these experiments.

Mr. Robert Loraine, besides being one of our leading actors, has acquired renown as an aviator, and when he is not crossing the Irish Channel, or making other records, he is engaged in wireless telegraph experiments which are likely to add to the sum of our knowledge as to what is required to secure success in this branch between the air and terra firma and the air and ships at sea. Mr. T. Thorne Baker, on the staff of the London "Daily Mail," has designed some special apparatus for this purpose, and the British & Colonial Aeroplane Co., of Bristol, have designed and manufactured a Farman biplane to enable the experiments to be made under the most favourable conditions. Wireless communication is said to have been maintained up to a quarter of a mile in the air, and valuable data was collected.

The importance of isolating wireless telegraph stations—*i.e.*, protecting them from the curious and the inquisitive—is dawning upon the authorities, and a number of the more important stations are being protected from "outside influences."

The first telegram originating in the air was a message received at the Eiffel Tower, Paris, from some special apparatus devised by a French engineer. This apparatus was taken up in the Clément-Bayard airship, and 50 miles from the tower a message was sent by M. Sabatier, the engineer-in-chief on board, to his family informing them of his imminent arrival.

Wolverhampton.—An inquiry was recently made into the Council's application for sanction to borrow £6,740 for extensions to the refuse destructor and power plant at Crown-street.

The Town Clerk explained that the proposal was to instal four extra cells, two boilers and another forced draught fan. With these additions they would be able to dispose of the town refuse as collected, and they would be able also to supply steam more regularly to the electricity department at a time when it was most required. That would warrant the electricity department in putting down a proper condensing plant, and when that was in operation it would effect a saving of about £300 a year. The output of the works would be increased about 50 per cent.

Workhouse Lighting.—The L.G. Board have sanctioned a loan of £1,160 for the electric lighting of Haslingden workhouse, repayable within 10 years.

West Ham Guardians are inviting tenders for wiring the new receiving homes at Wanstead.

York.—The city electrical engineer (Mr. J. W. Hame) has been authorised to prepare specifications of the additional plant required at the electricity works.

COLONIAL AND FOREIGN NOTES.

Argentina.—The "Review of the River Plate" states that Buenos Aires Corporation have been reminded by one of their officials that on taking over the undertaking at the end of 60 years from the signing of the contract with the Cia Alemaña Transatlantica de Electricidad (two years ago) the Corporation may have to pay about $100,000,000 for improvements.

It is expected that the contract with Agar, Cross & Co. (representatives of the British Westinghouse Co.) for the electrification of the *Mar del Plata* tramways will shortly be signed.

The electricity supply works at *Salta*, formerly owned by Señor B. Garcia, have been acquired by a new local company, with Mr. M. Henlitzka (ex-manager of the Cia Alemaña Transatlantica de Electricidad) as chairman.

At the Avenida (Buenos Aires) exchange of the United River Plate Telephone Co. a central battery switchboard was recently substituted for a multiple magneto board. The exchange has 4,000 subscribers.

Balearic Islands.—It is stated that Don Mariano Gual (Count of Ayamans) and Don Alfonso Chopitea have applied for a concession for the construction and working of an electric tramway from Cás Catalá to Palma station.

Constantinople.—As reported in our last issue, a convention for the supply of electricity in this city has been signed between the Minister of Public Works and representatives of a group composed of Hungarian (including Messrs. Ganz & Co.) and French syndicates, whose tenders were accepted. The concession is for 50 years.

Ecuador.—The report of Consul Cartwright on the trade of Ecuador for 1909 says the capital and objects of the electric light and car company at Guayaquil have been considerably extended during the past year.

The capital is now 1,500,000 sucres (£150,000), all locally subscribed, with power to increase the capital or to issue debentures. At present the electricity is generated by means of steam-driven plant, and the fuel principally employed is crude petroleum from the canton of Santa Elena. Arrangements are being made to obtain power by hydraulic turbines erected where there is water-power available near Bucay, on the Guayaquil and Quito Railway. The turbines are to be of 3,000 to 4,000 H.P. Electrical energy will be conveyed by a cable running about 54 miles along the side of the railway, from Bucay to Duran, and thence by cable under the river. It is understood that the contract has been given to a French firm and that work will shortly be commenced. The company supplies electricity to several industrial enterprises in the city, and will eventually be able to do a considerable business in this direction.

Italy.—The "Sole" (Milan) announces that the Ministry of Public Works have granted a concession for the construction and working of an electric railway from Argegno to Lanzo d'Intelvi, and have reported favourably on an application lodged by the Società Edison for the construction of an extension of the Milan-Affori electric tramway, from Affori to Varedo.

Mexico.—Two contracts have been entered into between the Government and the Cia de Tranvias de Mexico for the construction of electric tramways from Ixtapalapa to Puebla (about 100 miles) and from Santa Fé to Toluca (about 32 miles), forming extensions of the present electric system of Mexico City. The company is of Canadian origin, and the address is Indianilla, Mexico, D.F.

South Africa.—The Uitenhage (Cape Colony) electricity supply was formerly inaugurated on Aug. 25.

Cradock Municipality have decided to adopt electric lighting.

The message rate system of charging for telephone facilities in the Transvaal is said to have been a success, and has enabled a reduction of rates to be made.

It is stated that the Transvaal Government recently obtained a report by an expert in regard to a suggestion for the electrification of the Central South African railways.

Spain.—Senor D. José Riestra López (Marqués de Riestra) has been granted permission to utilise public lands in Freixa, Caramiñal, as a site for an electric power station.

Toronto (Canada).—The Toronto Electric Co. are applying for an injunction to prevent the completion of the municipal plant for the distribution of electric power brought from Niagara Falls over the Ontario Government transmission line, on the ground that the poles and wires in the streets will interfere with the company's system.

Water Power Development in Japan.—In a recent communication to "The Times" a correspondent (a member of the Japanese Board of Commerce and Agriculture) states that the development of the great water-power resources of Japan is a matter of national importance, and offers a sound and remunerative field for the investment of native and foreign capital.

About four years ago a concession was granted to a British syndicate (the Kobe Synd., Ltd.), jointly with a Japanese syndicate under the presidency of Mr. Sonoda, chairman of the Nobles Bank, and this syndicate comprised some of the leading bankers, financiers, and business men in our country. The propositions for power development were most

Digitized by Google

favourably reported on by a number of leading British and American hydraulic and electrical engineers. The project was highly approved of by the Government and warmly supported by Marquis Inouye, Viscount Hayashi, and your ambassador, Sir Claud MacDonald. It was decided to form a company with a capital of £1,280,000 for the development of 205,000 H.P. Half this amount was guaranteed by the Japanese, and it was understood that the other half would be found in England. About £500,000 was immediately subscribed by the leading men in Japan, including princes, noblemen, and all the first bankers and business firms. Such a thoroughly representative list was never before seen in connection with any company in Japan. But the British share of the capital was not forthcoming. Various reasons were given for this, and many alterations of terms, &c., were asked for, to all of which the Japanese side acceded. Extensions of the concessions were asked for and granted, but still no British capital appeared. After being held for many months the Japanese subscriptions were returned. The concessions are still held, and the Japanese ready to subscribe again. Great German and American firms were willing to finance and construct, but were refused. If the directors of the Kobe Synd., who belong, I understand, to contracting firms and members of the London Exchange, cannot finance the project after all these years are there not others to be found in London who can, to whom they might resign their seats? We Japanese would much prefer to do business with our allies than to be forced to do it with others.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Bournemouth.—The accounts of the Corporation tramways department for the year ended March last show capital expenditure £422,799 (increase £2,787). The amount of sinking fund applied in reduction of debt is £67,112, and the reserve or renewal fund shows an unappropriated surplus of £8,127.

Revenue was £85,540, working expenses £55,622, interest required £11,201 and sinking fund instalment £13,134, the net deficit being £2,263. 13,940,588 passengers were carried, 1,789,437 car miles run and 2,887,178 units used. Average speed per hour was 7·10 miles, total revenue per car mile was 11·47d. and working expenses, exclusive of power cost, 5·61d. and including power costs 7·45d. The average fare per passenger was 1·47d.

Dartford.—The capital expended on the electricity department to March 31 was £43,292, an increase of £2,192.

Receipts from the sale of current by meter were £7,602 net, from public lighting £1,207, meter rental, &c., bringing the total to £9,078. Total expenses were £5,405, leaving gross profit £4,033. Interest on loans required £1,245, instalments of loans repaid £1,905, income tax £55, and payments to tramways department as rent of light railway generating plant £221. The cost of condenser shed was £32, and after transferring £686 to reserve £1,405 was carried forward. The net profit on the year's working, after making a special provision of £489 for accrued loan instalments, amounted to £629, against £58 last year, when no such special provision was made. 1,046,615 units were sold (against 904,999), including 518,855 to private consumers for light and power, 405,185 units for traction and 122,575 for public lighting. There are 266 public lamps (against 264) and the total maximum supply demanded was 598 kw. (against 529 kw.)

In the report of the electrical engineer and manager (Mr. J. D. Pember) it is stated that during the past year 29 new services were laid and the equivalent of 868·8 c.p. lamps was connected. There were also nine motors (of 136 H.P.) connected, bringing the total to 588 H.P. The total works costs were 1·15d. per unit sold (against 1·43d.), and the total costs 1·94d. (against 2·16d.). The average price received per unit was 1·93d. (against 2·01d.), but the average price for private lighting was 3·58d. (against 3·58d.)

Ebbw Vale.—The annual report of the electrical engineer (Mr. Wm. Horsfall) states that the total capital expended on the electricity department at March 31 was £15,852, an increase of £213 during the past year.

£1,000 has been paid off, leaving the net expenditure of £14,852, but as the Council are authorised to borrow only £9,654, excess expenditure is £5,197. 17s. 10d. The sinking fund provided for the repayment of the loan of £9,654, stands at £1,274. 8s. 4d., and in addition £696. 11s. 8d. has been set aside for repayment of £5,197 17s. 10d. overspent, bringing the net amount overspent to £4,501. 6s. 2d. The number of consumers is 321, an increase of 84, and the number of lamps connected to the mains is equivalent to 7,162 8 c.p., an increase of 1,920. The number of units sold to private consumers amounted to 85,462, an increase of 11,563. Revenue from private consumers was £1,551. 2s. 1d., compared with £1,360. 8s. 3d. (for 73,899 units) in 1908-9. The gross profit for the year was £1,173, out of which £354 was paid as interest, and £160 paid to the Council's general accounts as interest on the amount overspent, and £608 as sinking fund, leaving a net profit on the year's working of £51, against a net loss of £58. £1,432 has been expended on free wiring installations, leaving £398 unexpended.

Leicester.—The accounts of the electricity department for the half-year ended June 30 show a net profit, after paying expenses and interest on capital and £3,343. 16s. 10d. on account of sinking fund, of £635. 3s. 6d.

Poplar (London).—The accounts of the electricity undertaking for the year ended March 31 last show net income of £42,251 from sale of current, an increase of £4,441.

Working expenses were £21,835, increase £2,368; gross profit £20,415, against £18,342. Net profit was £4,425 against £3,381. The total available surplus was £6,293, and it is proposed to pay various sums out of this of a capital nature which will reduce the balance to £5,336. The increase in units sold over the previous year was 2,035,116, and the net cost of coal £924 more, the extra units thus being produced at a cost of 0·109d. The cost per unit sold was reduced by 0·663d., equivalent to a reduction of £2,068 on the full output. The percentage of gross profit on capital was 8¼, increase 1 per cent. The average depreciation set aside by the metropolitan companies is slightly over 1¾ per cent., so that the comparable result with company dividends is claimed to be nearly 7 per cent. Loans redeemed during the year were £7,020, and £956 was paid out of revenue for work of a capital nature. Negotiations are in progress with regard to bulk supply. In the year prior to the change-over from carbon to metal filament lamps in street lighting, the cost for current was £1,625, and last year £1,170, a saving of £454. The cost of lamp renewals was in the first instance £162, and in the second instance £320, an increase of £158, showing a net saving of £296, without taking into account the number of lamps converted from gas in the interval. By the change the borough has gained in efficiency of street lighting from an initial 24 c.p. per post, and a steady diminution during use, to 50 and 100 c.p. per post, without any material reduction during life of lamps. The provision for depreciation (3¼ per cent.) is not unduly low, and the proposals for augmentation agreed with the L.C.C., will considerably increase this percentage in future. The net result, after providing for depreciation, is 5 per cent. profit on capital.

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1910 Edition of the Big Blue Book is READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 16th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1910 Big Blue Book, making it the most complete work of the kind ever published.

TENDERS INVITED.

Tenders are invited by WEST HAM Guardians for installing the electric light at the receiving homes in course of erection at Wanstead. Specification, &c., from the architect, Mr. Wm. Jacques, A.R.I.B.A., 2, Fen-court, London, E.C. Tenders to the office of the Clerk to the Guardians (Mr. Thos. Smith), Union-road, Leytonstone, London, N.E., by 10 a.m. Oct. 13. See also an advertisement.

Tenders are invited (till 2:30 p.m., Wednesday, Nov. 2) for supply to the Postmaster-General's department, New South Wales, of 1,000 25 c.p. metal filament lamps, with bayonet cap fittings, for 110 volts d.c. Tender forms, &c., at the Commonwealth offices, 72, Victoria-street, London, S.W. See also an advertisement.

Tenders are invited by Nov. 23 for supply of cable ironwork, c.i. pipes, earthenware conduits, switchboards, telegraph and telephone instruments, &c., to the Postmaster-General's Department in QUEENSLAND. Tender forms and specifications from the Commonwealth Offices, 72, Victoria-street, London, S.W. See also an advertisement.

Tenders are invited up to Nov. 2, 1910, for the supply of insulators, wire (covered phosphor-bronze and g.i. stranded) to the Postmaster-General's Department in QUEENSLAND. Tender form and specification from the Commonwealth Offices, 72, Victoria-street, London, S.W. See also an advertisement.

Tenders are invited by EDINBURGH Corporation for three steam turbines and d.c. generators, each of 1,200 kw., and condensing plant and interior parts of cooling towers, for their Dewar-place electricity

Digitized by Google

station. Copies of specification, forms of tender, &c., from the engineer, Mr. F. A. Newington, Dewar-place, Edinburgh, and specifications, conditions and drawings may be seen at, but not obtained from, the offices of the consulting engineer, Sir Alexander Kennedy, 17, Victoria-street, London, S.W. Tenders must be delivered at the office of the town clerk, Mr. Thomas Hunter, W.S., City-chambers, Edinburgh, by Oct. 10.

Tenders are wanted for electric lighting and power installations at the Scottish Exhibition of National History, Art and Industry at GLASGOW in 1911. Forms of tender from Mr. A. C. Freeman, 499, Sauchiehall-street, Charing Cross, Glasgow, to whom tenders by 10:30 a.m. Oct. 3.

The Directors of the METROPOLITAN RAILWAY Co. are prepared to receive tenders for the supply of general stores during 12 months ending Oct. 31, 1911. Forms of tender (No. 13, electric wires and cables; No. 14, electric lamps, carbons, switches, fuses, telephones, coils, &c.; and No. 15, insulating materials) from the Secretary, 32, Westbourne-terrace, London, W., to whom tenders by 10 a.m. Oct. 3.

HALIFAX Tramways and Electricity committee want tenders (by noon Oct. 17) for supply of a 1,500 kw. turbo-alternator, with condenser, two 750 kw. rotary converters, with transformers, switchboard, &c. Forms of tender from Borough Electrical Engineer.

LONDON County Council require tenders by 11 a.m. Oct. 11, for the road work and platelaying required for the reconstruction of the Highgate-road tramways for the conduit system, and for paving works of street widenings. Specifications from the Chief Engineer.

LONDON County Council also want tenders by 11 a.m. Oct. 5 for electrical installation work at the Poplar Coroner's Court and Hoxton House Schools, Shoreditch. Specifications, &c., from the Chief Engineer.

LONDON County Council want tenders by 11 a.m. Oct. 12 for wiring and fitting Sherington-road school, Greenwich, for electric light. Specifications from the Chief Engineer, Spring Gardens, S.W.

YORK Electricity committee want tenders by Oct. 7 for 12 months' supply of carbons, carbon brushes, carbon filament lamps, meters and time switches, motors, &c. Forms of tender, &c., from the City Electrical Engineer.

HACKNEY (London) Council require tenders by 7 p.m. Oct. 13 for supply of 90,000 pairs of white open-type arc lamp carbons. Specifications, &c., from the Town Clerk.

ISLINGTON (London) Guardians want tenders (by 4 p.m. Oct. 6) for supply and fixing of bells, fire alarms and telephones at the Workhouse, Upper Holloway, N. Specification from the Master of the Workhouse.

MANCHESTER Libraries committee want tenders by 9 a.m., Oct. 3, for electric wiring. Specification, &c., from the City Architect.

DERBY Corporation want tenders for steel and c.i. piping. Forms, &c., from the Borough Electrical Engineer.

Tenders are invited up to noon Oct. 17 for the supply of telegraph and telephone instruments and material (as per schedules 1 to 9) to the Postmaster-General's Department in TASMANIA. Tender forms and specifications at the office of the High Commissioner.

The Deputy Postmaster-General, MELBOURNE, will receive tenders until 3 p.m. Oct. 18 for supply of 23 miles of telephone cable (specification 284) and 500 composition insulators (specification 374) and until 3 p.m. Oct. 25 for 10,000 Cordeau insulators (schedule 373). Specifications, &c., from 72, Victoria-street, London, S.W. Local representation is necessary.

The Deputy Postmaster-General, MELBOURNE, wants tenders by 3 p.m. Oct. 25 for supply of electric lighting material (schedule No. 311). Specification, &c., from the High Commissioner.

ADELAIDE (S. Australia) Municipal Tramways Trust want tenders by Oct. 11 for supply of 1,750 tons of tramrails, 150,000 dogspikes and 1,200 tiebars and by Oct. 18 for bonding material.

Tenders will be received by the Minister of Telegraphs, G.P.O., WELLINGTON, N.Z., up to noon Dec. 15, 1910, for supply and erection of installations of wireless telegraphy at or near Doubtless Bay, Gisborne, Cape Farewell, Sumner (near Christchurch) and Bluff. Specification, conditions, &c., at the office of the Superintendent of Electric Lines, G.P.O., Wellington, and the office of the High Commissioner, 13, Victoria-street, London, S.W. Tenders must state the name of the country in which the apparatus, &c., will be manufactured.

The Ministry of Public Works, CAIRO, require tenders for electrical installations and refrigerating plant for the lunatic asylum in course of construction at Khanka. Specifications from the Chief of the Administrative Service, Ministry of Public Works, Cairo. Stamped paper for tenders is obtainable from Mr. A. L. Webb, Westminster, S.W. Tenders by noon Oct. 20. Legal domicile at Cairo is necessary in the case of this contract, and to obtain temporary domicile British firms must, before electing such domicile, formally advise the Consulate at Cairo of intention to do so, formally authorise the Consulate on their behalf and inform the Consulate of the address to which documents should be forwarded.

Tenders will be received at the Ministere des Colonies, rue Oudinot, 27, Paris, until Oct. 14 for the supply and laying of a submarine cable between LIBREVILLE and LOANGO (French Congo). Deposit of £2,000 required with all tenders, to be increased to £4,000 with successful tender.

Tenders are wanted by noon Oct. 31 for supply and erection of machinery, &c., for electricity supply and water supply systems for the town of BENI-SOUEF (Egypt). Particulars may be obtained from Mr. A. L. Webb, C.M.G., Queen Anne's-chambers, London, S.W. Local representation is necessary.

The Turkish Ministry of Commerce and Public Works want tenders by Oct. 28 (Nov. 10) for a concession for the construction and working of electric tramways in CONSTANTINOPLE and suburbs. A deposit of £13,500 (sterling) is required with each tender. Local representation is essential. Copy of specification (in French) may be seen at 73, Basinghall-street, London, E.C.

The "North China Herald" states that SHANGHAI electricity department require tenders by noon Oct. 10 for supply of electric heating and cooking appliances, and by noon Oct. 20 for 10,700 carbon and 15,000 metal filament lamps. Specifications from the Electricity Works, 31, Fearon-road, Shanghai.

TENDERS RECEIVED AND ACCEPTED.

Westminster Council has accepted the tender of Speedy, Eynon & Co. (at £47. 10s.) for wiring for additional lights of the large Caxton Hall, and for re-wiring consequent upon certain alterations. The tender of the same firm (at £45) was also accepted for altering the positions of the wires, switches, &c., adjoining the entrance to the large hall. The firm's tender at £20 for 100 metal filament lamps has also been accepted.

Coventry Corporation have placed an order with Ed. Bennis & Co. for supply of four sets of Bennis-Miller-Bennett chain-grate stokers for B. & W. boilers; and Kettering Council have placed an order with the firm for three independent coal elevators for feeding the hoppers of Bennis stokers on three Lancashire boilers. The Coventry order is a repeat.

West Ham Council have accepted the following tenders (lowest received):—

New Conveyor Co., ash elevator, £315; Aiton & Co., c.i. piping and valves, £163; Bruce Peebles & Co., motor, £125, and motor-generator, £152. 10s.; W. H. Allen, Son & Co., centrifugal pump, £121.

Barking Council has accepted the following tenders (the lowest received):—

Union Cable Co., 110 yds. 0·125 single cable, £9. 17s. 6d., and 440 yds. 0·008 twin cable, £23. 19s. 6d.; Western Electric Co., 880 yds. 0·05 three-core cable, £123, and 110 yds. 0·025 h.t. cable, £31.

Chelmsford Education committee have accepted the tender of the Banbury Electricity & Motor Co. for wiring Trinity-road schools and supplying fittings at £175.

Knottingley Education committee have accepted the tender of J. Richardson for installing electric bells at Rope Walk schools at £16. 4s.

Heckmondwike Council have accepted the tender of the Council's Electrical Engineer for wiring the cemetery lodge.

Venner & Co. recently supplied nine electric meters to the Bengal-Nagpur Railway electrical department.

Mansfield Council have accepted the tender of B. Meggitt for maintaining the electric fire-alarms.

Radcliffe Council have accepted the tender of W. Brierley for wiring the new Council offices.

Chippenham School governors have accepted the tender of Edwards & Armstrong for wiring the chemical laboratory and gymnasium.

Dudley Education committee have accepted the tender of Whittaker Bros. for wiring the new schools at Holly Hill.

Swansea Harbour Trust have accepted the tenders of Crompton and the British Westinghouse Co. for electrical plant at the docks.

Battersea (London) Council have accepted the tender of Pooley & Austin for switchboard, &c., at £120.

The tender of the Urban Electric Supply Co. has been accepted by the Grantham Guardians for electric pumping plant.

The South Indian Railway Co. recently placed orders with J. Stone & Co. for 26 dynamos and 26 switches for train lighting, and also 875 storage cells; Siemens Bros.' Dynamo Works for electric lighting cables, and the Wardle Engineering Co. for electric lighting materials.

Digitized by Google

We are informed that the Trenton Power Co. (Canada) have placed an order with Jens Orten-Böving & Co. for four turbines of 1,500 H.P. under 20 ft. head, complete with governors; and the Chicoutimi Pulp Co. (Canada) an order for two turbines of 4,500 H.P. under 75 ft. head.

BUSINESS NOTICES.

The Glasgow office of the Western Union Telegraph Co. has been removed from 49, Gordon-street to 113, Hope-street.

W. V. Waite & Co. (Ltd.), 31, Queen-street, Cardiff, have been appointed South Wales district agents for Bruce Peebles & Co.

Mr. J. M. M. Munro has severed his connection with Messrs. Anderson & Munro, and will devote himself entirely to consulting work at 108, Douglas-street, Glasgow. Mr. Munro has had extensive experience in country house lighting, power installations, street lighting, &c.

Messrs. T. & E. Wannbacher, engineers, merchants, &c., have removed their London office to 5, Appold-street, Finsbury, E.C. Telephone No. (6448 Central) and telegraphic address ("Wannbacher London") remain as at present.

Mr. F. Peake Sexton, A.R.C.S., A.M.I.E.E., has opened offices at Clarence-chambers, London-road, Kingston-on-Thames, where he will carry on business as consulting electrical engineer and dealer in electric lamps, fittings, &c.

The Ruberoid Co. have recently completed an extensive factory at Brimsdown, Middlesex, for the manufacture of the well-known Ruberoid roofing, damp course, flooring, sarking felt, insulating papers, insulating varnishes, and the well-known P. & B. tapes.

The materials manufactured by this company are well known throughout the electrical industry, particularly the P. & B. insulating varnishes and tapes. The company have recently brought out an interesting catalogue of preservative paints, which with full sets of samples of all materials manufactured and catalogues, will be sent to bone fide inquirers.

Patent Development.—The proprietor of patent No. 21,181/1905, for "Improvements relating to electrical measuring instruments," desires to enter into arrangements, by licence or otherwise, for exploiting same in this country. Applications to Messrs. Haseltine, Lake & Co., 7 and 8, Southampton-buildings, Chancery-lane, London, W.C.

Onewatt Lamps.—Messrs. Siemens Brothers incandescent lamp and fittings department (Tyssen-st., Dalston, N.E.) inform us that they are placing on the market a range of 50-volt "Onewatt" lamps, 10 c.p. and 16 c.p., in bell-shaped and spherical bulbs. They are now listing battery lamps, 13 to 16 volts, 100 c.p. lamps, 200 to 250 volts, and 10 c.p. and 16 c.p. lamps, 20 to 50 volts, all of the "Onewatt" type with drawn tungsten filaments. The prices of the new 50-volt lamps are, we are informed, low, and Messrs. Siemens Brothers are prepared to supply quantities of literature regarding same, upon receipt of application accompanied by trade card. It seems probable that during the coming lighting season other types of "Onewatt" lamps will be placed on the market.

"Wood Craft."—We have received a copy of the first number of a new monthly journal entitled "Wood Craft," which is intended to be a technical journal for the woodworking and timber trades. The journal has hitherto only been published in the United States, but as there has been no paper exclusively devoted to the technical side of woodworking in this country it was thought "Wood Craft" would fill this gap. Judging from the character of the articles, which are well illustrated, and the variety of the topics dealt with in the present issue, the new journal should prove a useful addition to the ranks of technical papers. It is published monthly at 22, Henrietta-street, London, W.C., and the annual subscription is 8s.

CATALOGUES, &c.

SUNBEAM LAMPS.—We have received from the Sunbeam Lamp Co. an advance copy of the lamp section of their catalogue, which gives full details of their well-known manufactures, comprising both metal and carbon filament lamps. Both of these are British made. The catalogue also contains details of Sunbeam new carbon and metal filament battery lamps, which are specially adapted for motor-car work.

LEUCONIUM LAMPS.—The Stearn Electric Lamp Co., 47, Victoria-street, S.W., have sent us a catalogue in which are illustrated and described their well-known Leuconium lamps. These are suitable for voltages up to 250, and are made in a number of shapes and sizes. Details are also given of this firm's well-known "Nevaout" lamps.

"SPOOKIE" NIGHT WATCH LANTERNS.—Simplex Conduits (Ltd.) have sent us a card illustrating a new design of lantern on the well known "Spookie" principle. Many improvements have been introduced into the new fitting. No glue is used in fixing the roof piece which prevents the shade from coming apart owing to the heat of the lamp. The frame of the lanterns is made up of specially thick card, which we are informed closely resembles wrought iron.

ELECTRIC BELLS AND ACCESSORIES.—Messrs. Siemens Bros. & Co. have sent us a catalogue dealing with this subject. It contains illustrations and details of a large variety of domestic bells of all patterns. A number of special lines of indicators have also been introduced and especial attention may be drawn to water-tight bells, with a diaphragm device for both out-door and mining purposes.

ELECTRIC CRANES AND HOISTS.—The Witton-Kramer Electric Tool and Hoist Co. have sent us a well illustrated catalogue in which is shown a variety of electric hoists and transporting appliances manufactured by them.

ALLGEMEINE APPARATUS.—The Allgemeine Elektricitäts Gesellschaft (Berlin) have sent us three pamphlets dealing respectively with Automatic Voltage Regulation on the Tirril System, the Application of various types of Motors, and with Totally Enclosed Switch Boxes. A large amount of useful technical information is contained in all of these.

BANKRUPTCIES, LIQUIDATIONS, &c.

An application for the discharge of Frank Sheppard, electrician, 4, Haslett-road, Kensington, London, W., will be heard Oct. 18 at Bankruptcy-buildings, London, W.C.

The Telewriter Synd. (Ltd.), having sold the telewriter and other assets to the National Telewriter Co. (Ltd.), and having gone into voluntary liquidation, creditors are required to send particulars of their claims to Mr. J. Craggs, 3, London-wall Buildings, London, E.C., by Nov. 10.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

*NOTE.—The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked * are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. Names within parentheses are those of communicators of inventions. When complete Specification accompanies application, an asterisk is affixed.*

July 21, 1910.

17,312 CHADBURN'S (SHIP) TELEGRAPH CO. & GRANT. Ships' and analogous telegraphic apparatus.
17,322 KESSELS. Printing telegraph instruments.
17,330 HALL. Electric generators.
17,336 HANNEMANN. Batteries.*
17,340 & 17,341 ADAMS MFG. CO. (Cutler Hammer Mfg. Co., U.S.) Motor controller circuits.*
17,344 ELECTRIC & ORDNANCE ACCESSORIES CO. & GARNER. Electric circuits, closers or starters for use in connection with electromotors and the like.*
17,349 ELECTRIC AND ORDNANCE ACCESSORIES CO., GARNER & MUELLER. Controllers for use in connection with electric-motors.
17,369 BLECKLY. Arc lamps.
17,380 ENGEL. Trolley guard attachment for electric tramcars.*

July 22, 1910.

17,399 ATKINSON. Construction of continuous-current electric generators and motors.
17,405 WHITELEY & MOSS. Means for resetting tramcar and like lifeguards.
17,415 CHAMBERLAIN & HOOKHAM & SPRAGUE. Prepayment electricity meters. (Addition to No. 3,250/10.)*
17,425 INCLEDON & INCLEDON. Connecting electrical conduits to their fittings.
17,447 BROWNE. Portable apparatus for the softening and purification of water by means of electricity.
17,469 EISNER. Manufacture of filaments for incandescing electric lamps.*
17,477 MAYOR. Electric conductors.
17,482 TUCKER. Current collectors for overhead electrical railways.

July 23, 1910.

17,498 CLAPHAM. Method and means for changing the trolly connection upon electric tramcars and the like.
17,523 JUDD & HARDIE. Telegraph relays.*
17,532 MCCLEAN. Time and destination indicators for tramways, railways, and like systems.

July 25, 1910.

17,597 CROSS. (Franz Krizik, Austria.) Electrically-actuated brakes.*
17,624 DUNOYER. Instruments for measuring the intensity and variations in the intensity of magnetic fields. (Date applied for, 18/8/09.)*†
17,641 KARAVODINE. Secondary batteries or storage cells.
17,650 HELFENSTEIN. Electric furnace with a receptacle for the charge arranged on the enlarged furnace chamber. (Date applied for, 27/7/09.)*†
17,658 VENNER & GRIESBACH. Switches.

July 26, 1910.

17,684 VENNER. Resistances for electric heating apparatus.
17,685 RICHMOND. Galvanic batteries.
17,694 MALSON. Electrical fuses.
17,731 SIEMENS BROS. DYNAMO WORK. (Siemens-Schuckertwerke G.m.b.H., Germany.) Arrangements for controlling the speed of induction electric motors.*
17,782 MYERS. X-Ray screen or shield.*

July 27, 1910.

17,818 HOPE. Fusible cut-outs for controling electric circuits.
17,819 GOLDSTONE & LIGHTFOOT. Electrical cord grips.
17,873 UPTON. Means and appliances for removing and replacing electric light or like bulbs in their sockets
17,874 MUNRO & RAILLESS ELECTRIC TRACTION CO. Electric traction systems.

July 28, 1910.

17,904 SCHOLEFIELD. Electric switches of the quick-make and quick-break type.
17,915 TAYLOR. Operating the switches or points in tramways and the like.
17,917 ALLOTT & CHEERS. Making copies of tracings and the like by means of electric light
17,991 SIMPSON. Generation of electric energy and apparatus therefor.
17,994 SIEMENS BROS. & CO. (Siemens & Halske Akt.-Ges., Germany.) Automatic telephone exchange circuits.*
17,995 SIEMENS BROS. DYNAMO WORKS. (Siemens Schuckertwerke G.m.b.H., Germany. Control devices for electric cars on routes in which two different voltages are supplied.*

July 29, 1910.

18,054 KRAMER. Inductive wireless telephone installations.
18,073 ROGERS. System of cutting out or electrically interlocking sockets and plugs in electric circuits.
18,095 BOSCH. Magneto-electric machines. (Date applied for, 15/10/09.)*†
18,098 SEWELL. Device for use in connection with a telephone to facilitate the recording of calls and messages.
18,115 BERRY. Electrical heating apparatus.

July 30, 1910.

18,136 VERITYS & PIPKIN. Electrical heaters or stoves of the radiator kind.
18,151 HAEFELY. Winding apparatus for coils or the like for electrical or other apparatus.*
18,180 BURNEY & BELL. Inter-communication telephone systems.
18,190 & 18,191 ADAMS MFG. CO. (Cutler Hammer Mfg. Co., U.S.) Controllers for electric motors.*
18,195 BROWN, BOVERI & CO. (Akt.-Ges. Brown, Boveri et Cie., Switzerland. Dynamo) electric machinery. *
18,197 LEITNER. Dynamo-electric machines. (Addition to No. 8,219/10.)*

August 2, 1910.

18,217 STEVENSON & WILLIAMS. Disconnecting a fitting, mounted perpendicularly over a supporting column or ledge.
18,236 SUGDEN. Telephone instrument whereby the transmitter may be cut out of the telephonic circuit.
18,241 WARDLE, jun. Lamps or lanterns for incandescent electric lamps.
18,253 KESSLER & KESSLER. Magnetic separators.*
18,295 ANDERSON. Manufacturing spark plugs.*
18,302 BLOXAM. (Société Debauge et Cie., France.) Machine for squirting tubes or wires of lead, or for sheathing cables with lead.
18,306 ADAMS MFG. CO. (Cutler Hammer Mfg. Co., U.S.) Means for controlling dynamo-electric machines.*
18,307 WARBURTON. Combined reciprocating enignes and turbo-electric generator and motors*

August 3, 1910.

18,333 KRAMER. Inductive wireless telephone installations.
18,344 FAIRWEATHER. (Hart Mfg. Co., U.S.) Switches.*

18,470 JOHNSON & BILLINGTON. Electricity meters.

August 5, 1910.

18,528 SIEMENS SCHUCKERTWERKE G.M.B.H. Electrical fuses. (Date applied for, 11/8/09.)*†
18,545 DYMOND. (Gesellschaft für Drahtlose Telegraphie m.b.H., Germany.) Producing but slightly damped electrical oscillations by the shock excitation method.*

August 6, 1910.

18,577 AITKEN & BRITISH INSULATED & HELSBY CABLES. Telephone switchboards.
18,591 A. P. LUNDBERG, G. C. LUNDBERG & P. A. LUNDBERG. Switches.*
18,608 DARWIN & CAMBRIDGE SCIENTIFIC INSTRUMENT CO. Electric controlling apparatus.

August 8, 1910.

18,622 BRAMPTON & THORNEYCROFT. Manufacture of conduit fittings for electrical and like purposes.
18,631 LANCHESTER. Propulsion of vehicles by combination of prime mover and electrical storage.
18,656 RENTON. Flexible cord attachment for electric lamp-holders.
18,658 JUDD, SCHAEFER & HARDIE. Screening of cables.
18,678 VIETTE. System of control and apparatus for indicating electric calls. (Date applied for, 19/10/09.)*†

August 9, 1910.

18,733 WILKINSON & FEARNLEY. Current collectors for electrically-propelled vehicles.
18,738 WEISSMANN. Holder for electric incandescent lamps. (Date applied for, 10/8/09.)*†
18,742 GILLIATT & EXCESS INDICATOR CO. Overload indicators.*
18,786 TOBIAS. Measuring and indicating the ratio of electrical forces and turning moments.*

August 10, 1910.

18,801 WHEELWRIGHT & MOXON. Lampholder attachment for the protection of flexible cable against fire and lamp filaments against vibratory motion.
18,821 GILL. Sheath for electric lamps.
18,837 SIEMENS BROS. DYNAMO WORKS. (Siemens-Schuckertwerke G.m.b.H., Germany.) Stator windings for single-phase electric induction motors.*
18,848 SIEMENS BROS. DYNAMO WORKS. (Siemens-Schuckertwerke G.m.b.H., Germany.) Starting arrangements for single-phase alternating-current series motors.*
18,867 B.T.-H. CO. (A.E.G., Germany.) Devices for securing wires or conductors in place.
18,868 B.T.-H. CO. (G.E. Co., U.S.) Signalling systems.
18,869 PRICE. Switches for working in connection with dynamo, motors, accumulators, and the like.

August 11, 1910.

18,916 MIDGLEY & VANDERVELL. Fittings for use in connection with electric incandescent lamps.*
18,935 BROWN. Electric telegraphy.
18,948 NORTH & WARD. Electric signalling.

August 12, 1910.

18,972 BARRY. Method of and appliances for greater safely in distribution for electric light and power circuits.
18,999 PATTISON. Holders for shades for electric incandescent lamps.
19,030 ARSEM. Filaments and the like for electric incandescent lamps. (Date applied for, 18/8/09.)*†
19,031 B.T.-H. CO. (G.E. Co., U.S.) Signalling systems. (Addition to No. 18,868/10.)
19,033 BEIGE. Incandescent electric lamps or like holders. (Date applied for, 12/8/09.)*†

August 13, 1910.

19,071 DAVIES, KENT & DAVIES, KENT & STEWART. Switches.*
19,075 JOHNSON & BILLINGTON. Recording mechanism of integrating electricity meters and other instruments.
19,077 SIEMENS & HALSKE AKT. GES. Manufacture of metallic filament incandescent lamps. (Date applied for, 9/6/10.)*†
19,093 HARDINGHAM. (Hartmann & Braun Akt.-Ges., Germany.) Electrical measuring instruments.*
19,095 A.E.G. UNION ELEKTRICITATS-GES. Manufacture of tungsten filaments. (Date applied for, 14/8/09.)*†

SPECIFICATIONS PUBLISHED.

1909 SPECIFICATIONS.

9,066 GARDE & ADAMS. Electrodes of secondary batteries.
10,665 ALLGEMEINE ELEKTRICITATS GES. Alternating electric current commutator machines having two working and two exciter windings. (Date applied for, 6/5/08.)
12,452 FISHER. Electric plugs.
14,212 TAYLOR. Charging and discharging electric accumulators or secondary batteries. (Cognate Application, 16,522/09.)
15,681 THOMAS & THOMAS. Switches.
16,621 RENNIE. Electric measuring instrument.

COMPANIES' MEETINGS AND REPORTS.

BRITISH THOMSON-HOUSTON CO. (LTD.)—Mr. J. F. Nauheim, who presided at the meeting on Wednesday, said the accounts showed a distinct improvement on those of last year, but did not, in the opinion of the directors, warrant the payment of a dividend. The company had to meet severe competition, both at home and abroad, and it was only by the strictest economy that they were able to cope with the difficulties of the position. The factory had been enlarged, and he hoped the shareholders would reap the benefit of that next year. The company now owed the General Electric Co. (of New York) £174,000, against £161,000, which was the corresponding figure in the previous year's balance-sheet, while sundry creditors had decreased from £122,000 to £120,000. Apparatus, meters, supplies, &c., stood in the books at £298,000, having increased from £255,000 the year previous, as a result of increased trade. Sundry debtors had decreased from £244,000 to £234,000.

DICK, KERR & CO. (LTD.)—At the ordinary general meeting yesterday (Thursday) the Chairman, Mr. John Kerr, said, in moving the adoption of the directors' report (abstracted in our last issue), he wished, before proceeding with the business, to make a brief reference to the great loss the company had sustained in the tragic death of Mr. George Flett, their managing director. Mr. Flett was associated with the company for nearly 30 years, and ever since the formation of the company as a limited liability company he had acted as a managing director. His early demise, in the fullest business vigour, left the Board with nothing but one great regret. Mr. Rutherford who had for a number of years acted so ably as assistant managing director, had been appointed managing director. Regarding the past year he was sorry to say the views he expressed at the last meeting, and he might also include the year before, as to the extreme competition in the electrical trade had proved only too true. With a demand none too brisk prices were likely to rule low, but in many cases figures were quoted by some firms below the cost of production. In times of depression all industrial concerns had to face restricted profits, but there was a point where discretion should cry a halt. Foreign competition also helped to aggravate matters. After three years of dull times, a period seemed at hand when there would in many directions be a great expansion of electrification in this country and abroad. The year now being dealt with must be equally a disappointment to the shareholders and the directors, but the directors, without holding too optimistic views, were of opinion that the work at present on hand and in prospect, made the outlook distinctly encouraging. In matters of depreciation and other provisions everything had been dealt with in the most careful and conservative manner, as in the past, the policy of keeping in reserve a goodly sum in times of prosperity had been fully warranted. The directors felt justified in trenching on the carry forward on this occasion, but it was their earnest hope that it would be the last. The financial position was one of comfort. They had in bills £22,565. 16s., cash £69,949. 18s. 10d., and investments £139,227. 18s. 8d., or together £231,743. 13s. 6d. Regarding the investments, at the price at which they stood in the books the return was a little over 6 per cent. per annum. After due consideration, the Board decided to take up the manufacture of steam turbines, and arrangements had been concluded to make turbines under the Bergmann patents. It was hoped that that departure would be the means of increasing their business in large alternators, for which they had a good reputation. The works had been maintained in a high state of efficiency and everything was being done to cheapen the cost of production while maintaining the highest standard of workmanship. It would be to the ultimate advantage of financiers as well as the advantage of their industrial concerns if they could use their

Digitized by Google

influence to see that as far as possible the money provided by the British investor was expended as regards material in providing employment for their own people. German and French financial methods were an object lesson in that respect. He concluded by expressing the directors' thanks to the staff for their zeal in promoting the interests of the company.

In reply to a shareholder, who asked why there had been this sudden outburst of competition during the past two or three years and remarked that, apart from the Board of Trade returns, he did not think individual companies had found the last two or three years particularly favourable, the chairman said there was not work to go all round. Some very large works were put down with the idea that there would be a very large quantity of work at once, but that had not been realised. He thought it was only Mr. Lloyd George who had seen the great boom in trade. None of them (the manufacturers) seemed to have realised it.

The report and accounts were adopted.

DIRECT WEST INDIA CABLE CO. (LTD.)—At the meeting last week Mr. T. Skinner presided and moved the adoption of the directors' report for the year ended June 30. The net result of the year's working was an available balance of £4,530. 15s. 3d., compared with £5,189. 11s. 1d. for the previous year. An interim dividend of 3 per cent. (tax free) had already been paid, and it was proposed to make a further equal payment (tax free), leaving £2,730. 15s. 3d. to be carried forward. The balance to credit of revenue was last year £33,965. 3s. 7d., and this had been debited with £900 applied to dividend and with £4,069. 18s. 5d. expended in renewals and repairs during the year, and credited with £2,730. 15s. 3d. surplus revenue of the past year, bringing the amount to £31,726. 0s. 5d. In November last the Turk's Island–Jamaica section of cable was damaged by floods in Bull Bay, Jamaica, the repair of which involved the large expenditure above recorded. During the year debentures have been paid off to the amount of £7,500, leaving £36,000 outstanding. The report and accounts were adopted.

DUNDEE, BROUGHTY FERRY & DISTRICT TRAMWAY CO. (LTD.)—At the meeting on Tuesday the chairman (ex-provost Brownlee) said that notwithstanding a falling off in receipts of £117, almost wholly attributable to the weather in the last week of the financial year, there was a saving in working expenses of £422, which enabled them to record a dividend of 2 per cent. to be paid on the ordinary shares. They had a very steady business with drawings that could always be depended on, and they expected to be able to keep down the expenses to the level of last year. The line was being kept up out of revenue in good repair.

HALIFAX & BERMUDAS CABLE CO. (LTD.)—Mr. T. Skinner, who presided at the meeting last week, said that the net result of the year's working to June 30, was an available balance of £5,737. 11s. compared with £3,312. 13s. for the previous year. An interim dividend of 2½ per cent. (tax free) had already been paid, and it was proposed to make a further equal payment (tax free), leaving £3,237. 11s. to be carried forward. The balance to credit of revenue account, which was last year £18,439. 5s. 2d., had been debited with £1,250 applied to dividend, and credited with £3,237. 11s. surplus revenue of the past year, and now stands at £20,426. 16s. 2d. The company's cable has worked efficiently. During the year £10,000 debentures have been paid off and the debenture debt is now extinguished.

HOBART ELECTRIC TRAMWAY CO. (LTD.)—The directors' report states that the traffic and general receipts show a substantial increase as compared with any previous year. Owing principally to the fact that a less sum was required to be expended on repairs, maintenance of permanent way, &c., the total working expenses show a reduction, and the net profit (after providing for interest, &c.) was £8,281. A dividend on the shares at the rate of 5 per cent. per annum (or 1s. per share), tax free, leaves £1,997 to be carried forward.

WESTERN UNION TELEGRAPH CO.—The report of the Western Union Telegraph Co. for the quarter ending Sept. 30 states that as a balance-sheet showing the financial condition of the company as at June 30, 1910 (at which date the fiscal year closed) is in preparation the usual quarterly statement is omitted pending submission of the balance-sheet. The net revenues of the quarter ending Sept. 30 inst., based upon nearly completed returns for July, partial returns for August, and estimating the business for September, will be about $2,000,000. Interest on bonded debt requires $433,062.50, and a dividend of ¾ per cent. about $747,770, leaving a surplus for the quarter of $819,167.50. These figures (as usual) do not allow for depreciation or reconstruction beyond current expenditures. The amount necessary to provide for depreciation and reconstruction has not yet been determined.

WILLANS & ROBINSON (LTD.)—The directors' report for the half-year to June 30 states that, after writing off £4,422. 1s. 4d. as depreciation, paying £4,216. 18s. 1d. debenture interest and £593. 6s. 5d. cost of upkeep of Queen's Ferry Works, the result of the half-year's trading shows a loss of £8,001. 14s. 3d. Added to £7,267. 2s. 6d. brought forward, this brings up the total debit standing against profit and loss to £15,268. 16s. 9d. Debentures representing £6,104 have been redeemed during the half-year out of the fund set aside for that purpose, and having been purchased at a discount the profit of the transaction has been transferred to reserve. The unsatisfactory result for the half-year is due to low prices prevailing and scarcity of orders obtainable during the whole of the year 1909. There has, however, been a steady improvement in the volume of orders booked during the present year, but although the amount of work in hand is now fairly satisfactory and orders are continuing to come in at an increasing rate, yet the prices obtainable are on even a lower scale than for the year 1909, and until there is a material improvement in this respect it will not be possible to show a profit. Every effort is being made to reduce costs so as to leave a margin on selling prices.

NEW COMPANIES, STATUTORY RETURNS, MORTGAGES AND CHARGES.

NEW COMPANIES.

ALLMANNA SVENSKA ELECTRIC CO. (LTD.) (111,849.)—Reg. Sept. 23, capital £5,000 in £1 shares, to carry on the business of manufacturers of and dealers in electric, mechanical and other machines, appliances and apparatus, &c. Private company. First directors, J. S. Edstrom, J. L. Fuller, K. Hedin and S. H. Busch.

CARLTON ENGINEERING CO. (LTD.) (111,787.)—Reg. Sept. 19 capital £6,000 in £1 shares, to carry on the business of mechanical, electrical and general engineers, electricians, machinists, boiler makers, &c., and to adopt an agreement with A. A. Rupprecht & Co. Private company. First directors, A. A. Rupprecht, E. L. Grant and H. S. Sutherland. Reg. office, Carlton House, Regent-street, London, S.W.

COLONIAL AND FOREIGN TRADERS) (LTD.) (111,932.)—Reg. Sept. 22, capital £1,100 in £1 shares (100 founders') to carry on mercantile, transport, trading and financial business, and to acquire and turn to account any electric, hydraulic or other motor power, water and other rights, &c. Private company. First directors, F. M. B. Carter and H. M. King. Reg. office, 32, Great St. Helens, London, E.C.

WHIPPLE & CO. (LTD.) (111,883.)—Reg. Sept. 24, capital £2,500 in £1 shares, to take over the business of manufacturing electricians, electrical engineers and contractors carried on as "Whipple & Co." Private company. C. R. Whipple is first managing director. Reg. office, 9, Cook-street, Liverpool.

STATUTORY RETURN.

CONSOLIDATED ELECTRIC WORKS & APPLIANCES (LTD.)—In return dated March 10, 1910 capital is given as £5,000 in £1 shares. 3,002 shares taken up. £1 per share called up on 2. £2 paid. £3,000 considered as paid on 3,000 shares. Mortgages and charges, £3,840.

MORTGAGES AND CHARGES.

KIRLEW BROS. (LTD.)—Particulars of £1,500 debentures, created by resolutions of June 6, 1902, April 6, 1903 and May 3, 1907, have been filed, amount of present issue being £500. Property charged: Company's property, present and future, including uncalled capital. No trustees.

THOMAS L. SCOTT & CO. (LTD.)—Issue on Sept. 7 of £400 debentures, part of a series of which particulars have already been filed.

"Z" ELECTRIC LAMP MFG. CO. (LTD.)—Issue on Sept. 9 of £3,300 debentures, part of a series of which particulars have already been filed.

CITY NOTES.

MEMORANDA (Sept. 29).—Bank rate 4 per cent. (Sept. 29, 1910) Price of silver, 24⅛d. per oz. Consols 80—80⅛ for money and for account. Consols Pay Day, Oct. 5; Stock and Shares Continuation Days, Oct. 12 and 26; Ticket Days, Oct. 13 and 27; Pay Days, Oct. 14 and 28; Mining Shares Carry Over Days, Oct. 11 and 25.

PRICES OF METALS (London).—*Copper*, cash, 55½; three months, 55⅝. *Lead*, English, 13—13¼; foreign, 12¾—12⅞. *Spelter*, 23½—23¾. *Tin*, English, 157½—158½; foreign cash, 159; three months, 158½. *Iron*, Cleveland, cash, 48/10, three months, 49/8.

ANGLO-ARGENTINE TRAMWAYS CO. (LTD.)—The directors have declared an interim dividend of 3s. 6d. per share (less tax), being at rate of 7 per cent., on the ordinary shares for the half-year ended June 30.

BABCOCK & WILCOX (LTD.)—The directors announce an interim dividend of 10 per cent., compared with 8 per cent. a year ago.

BRISBANE ELECTRIC TRAMWAYS INVESTMENT CO (LTD)—The directors have decided to pay an interim dividend of 4s. per share (at rate of 8 per cent. per annum) on the ordinary shares, compared with 2s. 6d. per share last year.

CALCUTTA ELECTRIC SUPPLY CORPN. (LTD.)—The number of units delivered to consumers during the four weeks ended July 29 were 794,120, compared with 728,069 units in the corresponding four weeks of 1909. The figures for the four weeks ended Aug. 26 were 824,917 in 1910, compared with 735,625.

CITY OF SANTOS IMPROVEMENTS CO. (LTD.)—An interim dividend of 2½ per cent. on the ordinary shares has been declared, tax free.

EASTERN TELEGRAPH CO. (LTD.)—This company announce payment on 15th prox., of a dividend at the rate of 3½ per cent. per annum (less tax) on the preference stock for the quarter ending Sept. 30, and the second quarterly interim dividend of 1¼ per cent. on the Ordinary stock (tax free) in respect of profits for the year ending Dec. 31, 1910. The transfer books of the ordinary stock will be closed from Oct. 7 to 14 inclusive.

REUTER'S TELEGRAM CO. (LTD.)—The directors have declared an interim dividend of 4s. per share (at the rate of 5 per cent.), tax free, for the half-year ended June 30.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee have granted quotations to a further issue of £200,000 4½ per cent. perpetual consolidated debenture stock of the *Winnipeg Electric Railway Co* and £250,000 5 per cent. first mortgage debentures (in lieu of the scrip) of *Vera Cruz Electric Light, Power & Traction (Ltd.)*. The committee have been asked to appoint a special settling day in and grant a quotation to £256,800 5 per cent. 30-year first mortgage gold bonds of the *Calgary Power Co. (Ltd.)*

THE ELECTRICIAN:

THE OLDEST WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY, SCIENCE AND FINANCE.

ESTABLISHED, First Series (Weekly), 1861; Second Series (Weekly), 1878.

No. 1,690. [No. 26. Vol. LXV.] FRIDAY, OCTOBER 7, 1910. PRICE SIXPENCE (by post, 6½d.), Abroad 9d., or 18 cents, or 90c., or 80pf.

CONTENTS OF THE CURRENT NUMBER.

NOTES 1051
Institutions and Societies ..1054
Arrangements for the Week..1054
Manchester Corporation Electricity Supply Accounts ..1055
Electric Steel Refining. By D. F. Campbell 1056
Three-phase Arc Lamp with Four Carbons. By Aldo Righi.....1057
Hysteresis Loops and Lissajous' Figures, and the Energy Wasted in a Hysteresis Loop. By Prof. Silvanus P. Thompson, D.Sc., F.R.S. Illustrated. 1058
Electric Railway Catenary Trolley Construction.—*Discussion* 1062
Results Obtained by the Use of Car Meters on Tramways. By G. Bouton 1064
Experimental Apparatus for Wireless Telephony. Illustrated 1066
The Thomas Young Oration..1069
HYSTERESIS LOOPS AND HARMONIC ANALYSIS 1070
REVIEWS 1071
Die Fernsprechtechnic der Gegenwart [Hersen and Hartz]; Electric Power Conductors [Del Mar];
REVIEWS—*continued.*
Matriculation Magnetism and Electricity [Jude and Satterly].
Leakage Reactance. By J. Rezelman. Illustrated. ..1072
Electricity and Gas in Manchester 1076
The Prevention of Accidents in Mines. Illustrated 1077
Scales of Electrical Instruments. Illustrated 1078
Hampstead Electrical Exhibition 1078
Commercial and Industrial Notes:—
Osram Publicity 0179
A Large Electric Clock. Illustrated 1079
O.S. Wiring. Illus. 1079
V. B. Cleat Ceiling Roses. Illustrated 1080
New Trade Literature. Ill.1080
LEGAL INTELLIGENCE 1081
Municipal, Foreign & General Notes 1082
Electricity Supply and Tramway Accounts.....1086
Trade Notes and Notices ..1087
Patent Record 1089

NOTES.

Rival Departments at Manchester.

MOST of the more important towns have both a Gas Department and an Electricity Department, and where such is the case there must be great difficulty in maintaining true competition. Such competition is really only possible where the rival concerns are run by private enterprise and are entirely separate. Where the control of two such competing departments is in the hands of a single Council, as it must be in municipal working, it is almost a case of a house divided against itself. Such a position, however, must be accepted in many cases, and Manchester is an instance of this kind. Presumably there has been a little ill-feeling on the subject, for recently a conference was held between the two departments at Manchester, and a report has been issued, in which it is stated that no useful purpose can be served by one department criticising the other, and the conclusion is reached that the prices of each department are fixed on recognised principles. Further, it is stated that nothing valid can be urged against the methods of working without prolonged special study of the problems facing each department. This savours of a truce; but the really important part of the report, of which an account will be found in another column, appears to be that dealing with the question of sums paid in aid of rates. Apparently, the City Council exacts from each department an annual sum for this purpose. It appears to us that any such exaction must be extremely undesirable. There is little objection to small contributions for such a purpose when the undertaking is fully meeting its responsibilities in regard to depreciation, and indeed this may be the simplest method of disposing of a surplus, since dividends are not available for this purpose in municipal undertakings. It seems, however, more rational when there is a substantial surplus that the price of the commodity should be reduced. Parliament has recently shown itself averse to the wholesale use of profits for the relief of rates, and it has been laid down in the case of certain gas bills that a maximum of only 1 per cent. on the outstanding mortgage debts of the undertaking should be so paid. This basis has been accepted by the two departments, with the result that the Gas Department ought to contribute £12,127, whereas the Electricity Department should contribute £19,701. It is certainly a defect of this basis that it introduces an anomaly, for the Electricity Department, with a somewhat lower capital expenditure, is looked to for the larger contribution to the rates. Also, the more free the capital from debt, which generally means the older the undertaking, the less is the relative contribution to the rates. In some respects this may be reasonable, because an undertaking is then dependent less on the credit of the rates, but nevertheless a department must obviously be able to afford such contributions less readily when it has to meet heavy capital charges than when its capital has been somewhat relieved. There is little doubt that these contributions in aid of rates can only act in a way to retard progress.

IN many ways it would be better for the Manchester Electricity Department if the gas supply were in the hands of a company. The electricity undertaking would then be able to gird up its loins and carry the war into the enemy's camp. In the present state of affairs something in the nature of an armed truce appears to have been entered upon. From the point of view of organisation the Electricity Department and the electrical contractors in the district

Digitized by Google

are fighting gas on the most aggressive lines possible. The contractors have good showrooms, and appear to be keen in giving publicity to the various uses of electrical energy. The supply undertaking, however, suffers considerably from the fact that the Gas Department is the street lighting authority, not only for the city area, but for Greater Manchester. It is the experience of most large towns in which electricity is used for street lighting that that particular form of illumination constitutes a valuable advertisement. Manchester has denied this useful class of publicity to its Electricity Department. The latter Department has laid mains specially for street lighting, and is in a position to give the inhabitants of Cottonopolis a cheaper and better form of lighting for their streets than they have at present, but the Gas Department holds the magic wand of authority and practically nothing can be done. In what was once the township of Gorton the Electricity Department erected a number of enclosed arc lamps for the lighting of the principal streets, and the experiment proved so satisfactory that the Council arranged for the conversion of all the gas lamps. Before the work could be commenced, however, the township was taken into the City area, in which, of course, the Manchester Gas Department alone had authority to supply the street lighting. The electric lamps meantime remain in the streets of Gorton as witnesses to an extremely unsatisfactory state of affairs, for gas lighting alone is possible in the streets under the new conditions. It will be interesting to follow the future policy of both departments, and we look forward to the time when the electricity undertaking will be able to carry on a vigorous campaign without let or hindrance from the members of the Gas Committee. The march of progress will probably bring about some such development, because, considering the matter of street lighting particularly, Manchester will be constrained to follow the example of many other commercial and industrial centres in which electricity will have superseded gas.

Car Meters.

THE diversity of opinion which exists in regard to the relative advantages of watt-hour meters, ampere-hour meters and clock meters for indicating the skill of individual motormen is perhaps accounted for by the conflicting experience of various managers. This is especially brought out in the report of Mr. BOUTON to the Union Internationale de Tramways et de Chemins de Fer d'Intérêt Local, which is abstracted elsewhere in this issue. Thus, whereas several undertakings have found that the use of clock meters leads to increased wear and tear of armatures, commutators and brushes, due to the motormen starting their cars too rapidly, others have not experienced this disadvantage; in fact, two undertakings are in favour of this procedure on the part of their motormen. As Mr. BOUTON points out, however, this is largely a question of capacity of the motors relative to the work they have to do; and we certainly think too rapid acceleration is to be avoided if the life of the equipment is not to be unduly short. That the use of clock meters encourages the motormen to reach the parallel running position as quickly as possible, regardless of the current taken in the process, cannot be gainsaid, and for this reason ampere-hour meters are, we think, to be recommended; watt-hour meters seem to be an unnecessary complication, since pressure variations may usually be neglected. It has often been stated that a clock meter effects the same result as if the energy consumption were measured. That this is by no means so is evident by the tests recorded in Mr. BOUTON's report. These show that a classification according to the period of coasting by no means agrees with the classification in which the energy consumption is the basis of comparison. Thus, where 36 motormen were under observation, the motorman who showed the best result with a clock meter was placed eighteenth on the list when the men were classified on the ampere-hour basis. Similarly, the motorman who occupied the thirty-third position in the clock meter list had the third lowest ampere-hour consumption. The other figures also showed unmistakably that reliance cannot be placed on the clock meter method of controlling the motormen if the economical operation of the cars is the object, although, naturally, supervision of any kind is bound to lead to improved results.

Gas Mishaps.

"SEVERAL fires occurred in London through window curtains being blown against gas jets." The above short sentence, culled from the reports in the daily Press of last Sunday's gale, was probably passed over without thought by the majority of its readers. Such a sentence is, however, very significant at the present time, when fires of unknown origin are of only too frequent occurrence. When one considers the multitude of gas jets which are in close proximity to inflammable materials and that a draught may be sufficient to bring such materials into a position where they are liable to catch fire, one can only marvel that serious conflagrations are not more numerous. That the danger is accepted as to some extent inseparable from gas lighting is evident from the fact that such calamities are passed over almost without comment by the public and the Press; while the latter usually honours electrical mishaps of much less consequence with all the importance of a startling headline. In this connection the efforts of the "Journal of Gas Lighting" to attach the blame for the recent fires at Brixton to electrical apparatus, in spite of evidence that the fires were in no way due to the latter, does not savour of good taste. But perhaps it is a form of humour.

Personal.—We learn that Mr. Walter Clark, for many years works superintendent of the Electrical Power Storage Co. has resigned.

Interference with Street Lamps.—At the meeting of the Islington Borough Council this evening, the following report from the Lighting Committee (dated September 28th, 1910) will appear upon the agenda:—

"We have had under consideration a report from the Electrical Engineer calling attention to interference with one of the Council's electric lamps by officials of the Gas Light & Coke Co. The Company's attention has been directed to the matter and they have tendered a written apology, but we think it desirable that the Council should be made acquainted with the circumstances, as it will be necessary to recommend that legal action be taken against the Company if such interference is continued.

Our readers will remember that we commented recently on the incident of which the above is the sequel.

Northampton Polytechnic Institute.—The new generating station of the Institute, which has been installed at a cost of about £6,000, will be formally opened by the Chairman of the London County Council on Wednesday next.

Lighting of Side Streets in Boston (U.S.A.).—A recent article in the "Electrical World" on this subject is of interest, showing, as it does, that similar problems have to be overcome in America with regard to street lighting as over here. It appears that, after many weeks of investigation, the superintendent of streets, Mr. L. K. Rourke, has decided to advertise for minor street lighting on the basis of five year and ten year contracts, instead of placing the contract on a two year basis, as originally announced. Twelve thousand lamps are involved, and either gas or electricity may be used. The existing conditions as regards the gas lighting of minor thoroughfares are entirely unsatisfactory. The work is handled by a company which has held the field for about 22 years, and the gas is purchased for use by the city only after a considerable profit has been paid to the lamp company for its part in handling the gas, which in the first instance is supplied by the Boston Consolidated Gas Co. If electricity is used in place of gas all these middlemen's profits will be obviated, and the city will secure light with the minimum of trouble. Automatic lamp-lighting equipment is being investigated by the Street Department, but thus far without any results tending to show that these devices have reached a stage of development when they can be considered genuinely reliable. In some of the outer suburbs the Edison Electric Illuminating Co. of Boston has installed tungsten lamps with decided economy to the city as compared with gas lamps. The city authorities are trying to avoid any system which would involve a large investment in lamps and mantles, or any extended maintenance organisation. It is probable that there will be vigorous competition between electricity and gas for the contract which is about to be let.

A Master Patent for Electric Traction.—It seems rather extraordinary at this stage in the development of electric traction that discussions on fundamental patent questions should still be going on; but this is apparently the case, at least in the United States, for according to "Engineering News" the Schlesinger electric railway patent, which was applied for in 1885 when electric railways were in their infancy, and which is said to affect nearly all the electric railways in that country, has been in litigation for several years both as to its validity and its ownership. A decision given by Judge Bradford in the U.S. Circuit Court (Pennsylvania) on July 28, 1910, covers the following points: (1) Wm. M. Schlesinger was the original inventor, (2) the Allis-Chalmers Co. are the owners of the patent, (3) the General Electric Co. and the Hestonville, Mantua & Fairmount Passenger Rly. Co. have infringed upon the first claim of the patent, and (4) that profits derived by the infringing companies since December 15, 1896, may be recovered by the owning company. The application for this patent was filed on November 24, 1885, and the patent (No. 546,059) was issued September 10, 1895. The first claim, which was the basis of the suit, covers an electric railway system in which the working conductor (trolley wire or third rail) is divided into insulated or disconnected sections, each section being connected to the generator or 'bus bar at the power station through a separate feeder provided with an automatic circuit-breaker or other protective device. The ownership of the patent by the Allis-Chalmers Co. has been upheld by a previous decision of the U.S. Circuit Court of Appeals. In the present suit, an injunction has been issued against the use of, manufacture, or sale of the infringing apparatus by the defendant companies, and our contemporary is informed that, after hearing arguments, the Court refused to suspend this injunction pending appeal.

Cable Interruptions.	Date of Interruption.
Assab—Perim	July 8, 1909
Malta—Tripoli	April 20, 1910
Reunion—Mauritius	May 20, 1910
Latakia—Palura	May 26, 1910
Obock—Djibouti	June 24, 1910
Tourane - Amoy	Sept 25, 1910
Paramaribo—Cayenne	Oct. 1, 1910

Tests with a New Brake Shoe at Philadelphia.—A recent issue of the "Electric Railway Journal" mentions that the Philadelphia Rapid Transit Co. has been obtaining some remarkable results with a new type of brake shoe with regard to long shoe life, minimum wheel wear and high friction coefficients in braking. The first operating installation was made in May, 1910, and since that time about 1,000 shoes have been placed on both single and double-truck cars with hand or air brakes. These shoes are of the inset type, the body being made of a fine grade of iron, with a tread containing six cylindrical pockets 1½ in. deep and filled with cement. It has been found that these insets are a strong factor in eliminating the screeching common to many brake shoes. The inset composition is not affected by moisture, as was shown by its behaviour during six weeks of heavy rain, when the first shoes were placed in service. The pattern in use up to the present time has a groove or throat to receive the wheel flange for the full length of the shoe. However, in accordance with a suggestion that has been made, the new design will have a tread 2¼ in. wide and heel and toe guides only for the flange of the wheel. This change will bring all the braking on to the treads, and prevent the pinching or breaking of the wheel flanges. The older shoes have been scrapped at an average weight of 6½ lb., but the new pattern shoe, weighing 20 lb. originally, will not have to be discarded until it reaches 4 lb. Not one of the shoes has been removed from the hand-brake cars, and the railway company expects them to give at least a year's service before scrapping. The average life of 115 shoes taken off the air-brake cars was 10,173 miles. The rest of the air-brake shoes, constituting about 70 per cent. of the total, are still in service, so that the net average life should be several thousand miles more than the figure given. The drawback of the ordinary long-life shoe is its excessive abrasion of the wheel. This is particularly true of shoes made of such material as chilled or soft gray iron. However, the tests made with the new inset shoe by the Philadelphia Rapid Transit Co. show that it wears the wheels far less than cast iron steel-back brake shoes. The exact figures obtained or the action of both shoes on steel wheels were as follows: Inset shoe used 67 days, or 8,445 miles, wore off $\frac{3}{32}$ in.; inset shoe used 69 days, or 8,645 miles, wore off $\frac{1}{8}$ in.; cast-iron shoe used seven days, or 940 miles, wore off $\frac{1}{8}$ in.; cast-iron shoe used five days, or 740 miles, wore off $\frac{3}{32}$ in. On September 13, 1909, before the extended installation of the inset shoe, the railway company tested it for its frictional coefficient value in comparison with common cast-iron brake shoes. The test runs were made on a 3 per cent. down gradient 690 ft. long. The air brakes were applied when the cars were running at top speed. The results showed that with 50 lb. pressure the inset shoe equipment was stopped in an average length of 204 ft., or 59 ft. less than the cast-iron shoe equipment. Similarly, with 75 lb. pressure, the inset shoes enabled the car to be stopped in 158 ft., or 22 ft. less than the cast-iron shoe equipment.

The Hygienic Aspects of Illumination.—In a Paper on this subject read before the second Congrès International des Maladies Professionelles at Brussels last month, Mr. Leon Gaster pointed out how much, not only the workman, but also the employer, benefited by the maintenance of good lighting conditions. The question had recently been receiving much attention, both on the Continent and in America, while the Home Office were now making a special study of the question of the conditions of illumination in factories, and were providing for the collection of data bearing thereon. Good results in illumination could only be obtained by the joint efforts of the engineer, the oculist and the architect. The whole question of illumination depended upon the behaviour and well-being of the eye, and the medical profession were, therefore, intimately concerned. At the same time, new developments were constantly taking place, and newer and brighter sources, with the technical details of which the engineer was chiefly familiar, were replacing the old lights of the past. In one respect these new sources were notably different from the lamps they were superseding. The "intrinsic brilliancy," or "candle-power per square inch," was much greater, and the lights were there-

Digitized by Google

fore apt, if misused, to be dazzling to the eye. For this reason it was most essential to arrange the sources wisely, so as to avoid any tendency to glare, and especially in the case of workshops and factories where people were exposed to artificial light for long periods of time. Lights should therefore be placed outside the direct range of vision, and advantage should be taken of appropriate shades and reflectors to direct the light where it was wanted and to screen it in directions in which its brilliancy would be inconvenient. Again, there were many industrial processes, such as those in lamp factories, glass and iron works, welding operations, &c., where workers might be exposed to the rays of these bright illuminants, and proper methods of protection were most important. But it had been suggested that it was not only the intrinsic brilliancy that was harmful. Dr. Stockhausen and others had laid stress on the effect on the eyes of the ultra-violet invisible rays, and attributed the severe inflammation following incautious exposure to powerful lights to this cause: this question required further examination before definite recommendations could be made. It had also been suggested that the prevalence of cataract among glassworkers was due to the peculiar radiation given out by the molten material, and an inquiry was now being conducted into the matter. Yet another aspect of the subject which deserved to be emphasised was the tendency of bad conditions of illumination to lead to accidents. Naturally, mishaps were more apt to occur when the machinery could not be clearly seen. The Fidelity and Casualty Co., of New York, in a recent report placed defective lighting first in the list of causes of accidents.

British Standard Specification for Bayonet Socket Lamp Holders and Caps.—The latest report of the Engineering Standards Committee deals with this subject, and all will be agreed that it appears at an exceedingly opportune moment, for the advent of the metal filament lamp has brought with it a difficulty in regard to the fitting of any lamp cap into any holder in general use. This difficulty has, the Committee find, been very noticeable of late, and whether it is due to hasty manufacture or, on the other hand, to faulty gauging, the result is annoyance to the user and the possible loss of custom to the maker. Lamp makers would therefore do well to adopt the suggestions of the Committee as outlined in their specification, especially in regard to the question of the verification of their shop gauges. It should not be a difficult task to do away entirely with any tendency to non-interchangeability between lamp caps and lamp holders of different makes. The Committee, in a preface written by Dr. R. T. Glazebrook, point out that although they have kept in view the great desirability of interchangeability, they have been most careful not to interfere in any way with invention and progress. They also express their appreciation of the courteous assistance rendered by the makers. The present specification deals with holders for lighting purposes only, but we understand that the effect of heat on the ordinary lamp holder is being investigated experimentally at the National Physical Laboratory, and an addendum to the present report, dealing with lamp holders for use with radiators, may shortly be expected. The price of the present report is 5s. 2d., post free, and it may be obtained from any bookseller or direct from the offices of the Committee, 28, Victoria-street, Westminster. It is published for the Committee by Messrs. Crosby Lockwood & Son.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. J. Rezelman contributes an article on "Leakage Reactance."

A description is given of the wireless telephone apparatus devised by Mr. E. F. Huth, of Berlin.

At the meeting of the Iron and Steel Institute last week a Paper was read by Mr. D. F. Campbell on "Electric Steel Refining."

We give an abstract of the Paper "On Hysteresis Loops and Lissajous' Figures, and on the Energy Wasted in a Hysteresis Loop," read by Prof. S. P. Thompson before the Physical Society. This is also referred to in a Leading Article.

The report of Mr. Bouton on car meters, presented at the recent meeting of the Union Internationale de Tramways et de Chemins de Fer d'Intérêt Local, is abstracted in another column.

As a result of a conference between the Gas Department and the Electricity Department of the Manchester Corporation, a report has been presented as to the methods of working of the two departments and as to their respective contributions for the relief of the rates.

The accounts of the Manchester Corporation Electricity Department for the year ended March 31st last are analysed elsewhere in this issue.

Acton Council have agreed to transfer their electricity supply undertaking to the Metropolitan Electric Supply Co.

West Hartlepool Corporation have made an arrangement with the Seaton Carew Iron Co. for the utilisation of the waste heat of blast furnaces at the ironworks for generating electricity.

Another Telephone Subscribers' Protection Association has been formed, this time at Edinburgh.

An electric power scheme of considerable magnitude is briefly mentioned in a note headed "India." A company has been registered in Bombay with a capital of £1,134,000 in connection with this project, in which the Lahmeyer Co. is interested.

Loans for Electricity Supply.—An inquiry was held last week into the application of *Walsall* Corporation to borrow £23,225 for extensions of the electricity undertaking.—The Local Government Board have sanctioned a loan of £20,000 for an electricity supply scheme for *Dundalk*.—*St. Helens* Corporation have received sanction to a loan of £11,206 for extensions of the municipal electricity works.—*Stepney* (London) Council have applied to the L.C.C. for a loan of £7,150 for additional plant, &c., for the Limehouse generating station.—*Aston* Council have received sanction to loans amounting to £2,575 for electricity supply.—*Wigan* Corporation have received sanction to a loan of £36,000 for the electricity undertaking.—*Heston and Isleworth* Council are to borrow £3,048 for extensions of the electricity undertaking. An inquiry was held on Wednesday into the application of *South Shields* Corporation for permission to borrow £9,400 for their electricity undertaking.

Arbitrations.—Mr. Robert Hammond has been appointed arbitrator to determine the price to be paid for electrical energy for the next seven years by Paisley District Tramways Co. to Paisley Corporation. The proceedings will commence to-day (Friday).

Mr. Archibald Read has been appointed arbitrator in regard to the price to be paid by Winchester Corporation for the Winchester electricity works.

Mr. Archibald Read has given his award in the Torquay tramway arbitration to the effect that the consent of the Corporation to the use of the overhead system on Torbay-road has been unreasonably withheld.

Legal.—An interesting legal case, in which Mr. Justus Eck was successful in an action brought against the Union-Castle Mail Steamship Co., is reported. The result is of something more than personal interest—electric fan makers please note.

INSTITUTIONS AND SOCIETIES.

Institution of Civil Engineers.—The Council of this Institution have made the following awards in respect of Papers published in Section II. of the Proceedings for the Session 1909-1910:—A Telford Gold Medal to Major W. W. Harts, U.S. Army; a Watt Gold Medal to Mr. A. Trewby; a Crampton Prize to Prof. A. H. Gibson and Mr. A. Ryan; and Telford Premiums to Messrs. W. R. Baldwin-Wiseman, O. W. Griffith, W. E. Lilley, W. Corin, J. A. Saner and F. O. Blackwell. They have also awarded the Indian Premium for 1910 to Mr. C. W. Lloyd-Jones.

ARRANGEMENTS FOR THE WEEK.

MONDAY, October 10th.

JUNIOR INSTITUTION OF ENGINEERS.

7:30 p.m. Meeting at Caxton Hall, Westminster. Lecture on "The Law Relating to Engineering," by Mr. L. W. J. Costello.

GRADUATES' ASSOCIATION OF THE INSTITUTION OF MECHANICAL ENGINEERS.

8 p.m. Meeting at Storey's Gate. Paper on "Recent Improvements in Wood Working Machinery," by Mr. A. E. Harris.

WEDNESDAY, October 12th.

ASSOCIATION OF ENGINEERS-IN-CHARGE.

8 p.m. Meeting at St. Bride's Institute, Bride-lane, Fleet-street. Presidential Address on "The Ordnance Survey and the Design and Use of Machinery for Printing Maps," by Capt. H. R all Sankey, R.E.

Digitized by Google

MANCHESTER CORPORATION ELECTRICITY SUPPLY ACCOUNTS.

Whatever may be said as to the general development of electricity supply in this country, there is no doubt that Manchester is well to the fore in things electrical. From the early days of electricity supply the Manchester undertaking has been a centre of interest to electrical engineers, and during the last year or two the rapid progress made, particularly as regards power supply, has attracted more than usual attention. The total number of units sold by the electricity department during the year ended March 31st last was no less than 71,557,387, or over 90 units per head of population. This is, we believe, one of the highest figures recorded in this country. Of this total, about two-fifths is accounted for by electric traction, viz., 28,526,468 units, whilst private consumers required 42,886,223 units, public lighting being only responsible for the small amount of 144,696 units. Compared with the previous year's figures there is an increase of 5,736,201 units in the quantity sold to private consumers, an increase of 45,103 units, or 45 per cent., in the energy used for public lighting, and a decrease of 1,148,781 units in the amount of electrical energy supplied to the tramways.

As the maximum load increased from 31,118 kw. to 33,785 kw., the latter figure comprising a demand of 24,193 kw. for lighting and power and 9,592 kw. for traction, it will be seen that the load-factor is 24·2 per cent., compared with 24·6 per cent. a year ago, and 25·4 per cent. in 1907-8. This decline in the load factor is rather surprising in view of the extensive power supply developments in recent years. If the figures are analysed, it will be found that the traction load factor has increased from 33·3 per cent. in 1908-9 to 33·9 per cent. in 1909-10, whilst the load factor recorded for lighting and power during the last 12 months was 20·3 per cent., the same as a year ago. The total capacity of generating plant at March 31st was 45,300 kw.

In regard to the energy lost in distribution, or otherwise unaccounted for, this has reached the high figure of 17,175,300 units, or approximately 18 per cent. of the total quantity generated, which latter amounted to 95,542,254 units. The above figure of 18 per cent. is about 1 per cent. higher than in the previous year. This is due to a greater output to the high-pressure alternating-current network, the energy absorbed in the latter being necessarily higher than in the low-pressure continuous-current area.

Turning now to the financial statistics of the undertaking, the sales of current for lighting and power were £247,420, as against £231,648 a year ago, whilst the revenue obtained from the sale of current to the tramways department has decreased from £128,613 to £119,348. The net result is that the total income of £374,878 shows an increase of £7,031. As the total costs (including capital charges) amounted to £338,873, compared with £333,949 last year—a very satisfactory result considering the increased output—the balance shown is £36,005.

It will be seen, from our analysis of the expenditure below, that considerable economies have been introduced, and the total costs (excluding capital charges) now stand at 0·61d., compared with 0·66d. last year. There is little doubt, however, that a much lower figure will be reached as greater use is made of the new plant in Stuart-street station.

The following is an analysis of the expenditure during the past financial year, together with the cost of working per unit sold, the latter figure also being given for the previous year.

		Cost per unit sold. 1909-10.	1908-9.
Generating Costs.			
Coal, &c.	£63,239	0·21d.	0·24d.
Oil, waste, water, &c.	6,046	0·02d.	0·03d.
Salaries and wages at station	18,359	0·06d.	0·07d.
Repairs and maintenance	13,438	0·05d.	0·05d.
Total Generating Costs	£101,082	0·34d.	0·39d.
Distribution Costs.			
Salaries and wages	£15,373	0·05d.	0·06d.
Repairs and maintenance of sub-station machinery, meters, fuses, &c.	14,760	0·05d.	0·04d.
Miscellaneous	2,352	0·01d.	0·01d.
Total Distribution Costs	£32,486	0·11d.	0·11d.
Management Costs.			
Salaries and wages	£8,569	0·03d.	0·03d.
Printing, stationery, &c.	950	0·00d.	0·00d.
General establishment charges	1,552	0·01d.	0·01d.
Law and Parliamentary charges	536	0·00d.	0·00d.
Special charges	1,339	0·00d.	0·01d.
Total Management Costs	£12,946	0·04d.	0·05d.
Rents, rates and taxes	£34,684	0·12d.	0·11d.
TOTAL COSTS (ex. capital charges)	£181,197	0·61d.	0·66d.
Capital Charges.			
Interest	£69,311	0·23d.	0·24d.
Sinking fund and repayments	88,365	0·30d.	0·29d.
Total Capital Charges	£157,676	0·53d.	0·53d.
TOTAL COSTS (inc. capital charges)	**£338,873**	**1·14d.**	**1·20d.**
Revenue			
Sales of current	£367,702	1·23d.	1·29d.
Rental of meters	431	0·00d.	0·00d.
Rental of motors	4,791	0·02d.	0·02d.
Miscellaneous (less bad debts)	1,954	0·01d.	0·01d.
TOTAL REVENUE	**£374,878**	**1·26d.**	**1·32d.**
Balance (surplus)	£36,005	0·12d.	0·12d.

Of this balance, £23,822 is paid into the Renewals Suspense Account and £183 to the Reserve Fund Account, whilst the remaining sum of £12,000 is handed over to the city fund in aid of the rates. This last-mentioned contribution is a similar amount to that paid over to the rates a year ago. The Renewals Suspense Account showed on March 31st last a balance of £141,451, compared with £135,252 a year ago, the expenditure on plant discarded, &c., during the 12 months having been £20,553.

The generating costs given above are the combined costs for Dickinson-street, Bloom-street and Stuart-street power stations. The individual figures per unit generated are as follows :—

Stuart-street.		
Number of units generated	68,505,025	
Cost of fuel	£41,080	or 0·144d. per unit generated.
„ oil, &c.	3,968	or 0·014d. „ „ „
Salaries and wages	8,913	or 0·031d. „ „ „
Repairs and maintenance	7,266	or 0·025d. „ „ „

In comparing these figures with the combined figures given in the analysis above, it should be remembered that the latter are calculated per unit sold. Moreover, in comparisons between the results of the different stations, it must not be forgotten, as mentioned above, that the distribution losses are greater in connection with the high-tension transmission.

In connection with the extensions to the power plant during the year, the most interesting feature was the large Tudor battery installed. This is now in successful operation. The large extensions of steam plant and accessories at the Stuart-street station have also been brought to a satisfactory conclusion, and substantial improvements have been effected in the high-tension switchgear. As to extensions of mains, a net addition of 16¾ miles has to be recorded.

During the year the capital expenditure amounted to £111,924, mains accounting for £30,714 of this total, buildings and plant at Stuart-street station for £39,439, and plant and buildings at Dickinson-street for £21,688. The total capital expenditure to March 31, 1910, was £2,678,630, the various

ELECTRIC STEEL REFINING.*

BY D. F. CAMPBELL.

Summary.—The author discusses the general aspects of the use of electricity for the refining of steel, and describes the usual procedure with an electric furnace. Probable future developments in this country are also outlined.

The electric furnace is at present used in various works for the refining of steel from the Bessemer converter in the manufacture of rails and all classes of railway material and castings, and more commonly in connection with the basic open-hearth process for the manufacture of various products of intermediate quality, castings and tool steel of all kinds. These are the purposes for which it has been most widely adopted, notably in America, Germany and France, though it is also used for melting and refining charges of cold scrap of cheap quality for the manufacture of tool steel and small castings, and its high efficiency is now generally acknowledged. The refining of steel that had been previously melted was the first use to which the electric furnace was applied commercially; but now that single furnaces have been producing over 200 tons a day for more than 16 months, it is obvious that the field for the process has widened, and already many furnaces are in construction or operation in this country.

The author is of opinion that the electric furnace is especially suitable, and will be widely adopted, for any class of work in which raw materials of a high degree of purity are now used. A wider application for rails and sections may occur when working in connection with the Talbot furnace, for the charge can be taken to the electric furnace as soon as the carbon is down, and the necessity of removing the sulphur and getting a teeming heat is avoided, as this is done in the electric furnace both economically and completely. Thus the capacity of the Talbot furnace is substantially increased, and this covers the greater cost of electric refining. Again, in the case of a basic open-hearth plant, using 60 per cent. of molten pig iron and 40 per cent. of scrap, a 40-ton furnace might have 15 tons removed to the electric furnace for refining, and a similar charge put in every two hours. Thus the capacity would be increased, the quality improved, and, in addition, a reduction in the cost of raw materials can also be made in some cases, as a low quality of pig iron can be used.

Similar conditions occur when working in conjunction with an open-hearth plant for making castings, and a thoroughly dead melt and extreme fluidity can be obtained, while the commonest raw materials can be used, and refined completely. This gives economy both in the amount of gits and runners, and also in the reduction of wasters. Even in the case of foundries engaged in ordinary open-hearth casting work, in which the margin of profit is now exceedingly small, the electric furnace is considered necessary for an improvement in quality, while in a small foundry making light and intricate castings from crucible steel, an economy of several pounds per ton may be expected to result from the adoption of the electric furnace, judging from the reduction of the costs in works in Germany where crucible furnaces were replaced by this process. There is little doubt that crucible steel, Swedish billets, and products of intermediate quality, such as are used for the Sheffield trade and by tube-makers of Staffordshire and South Wales, can be economically replaced by steel refined by electricity, and made in Middlesbrough, Cumberland, or the larger steel works in the Sheffield and Rotherham districts.

The use of the electric furnace is not likely to become general for rail steel manufacture at the present time, except in cases where the conditions are exceptional. In certain cases, such as at South Chicago, it has been adopted for that purpose owing to the economic conditions, notably the scarcity of good Bessemer ores and the demand for better rails. The electric furnace in such cases may save Bessemer plants from the scrap heap, or, at any rate, prolong the life of present installations, and at the same time make it possible to produce rails of a quality better than the best open-hearth steel, thus avoiding heavy capital expenditure.

In the electric furnace, almost any degree of refining can be economically effected, and the removal of sulphur, phosphorus and oxygen is especially easy. This is probably due to at least three causes: (1) The intense heating of the slag, which is the place at which refining takes place. Owing to this high temperature and the extreme fluidity of the slag, the rate of the refining reaction is very great, because the velocity of reaction rises very quickly for high temperatures, and not in direct proportion to the temperature. (2) The extremely basic slag that can be kept in a very fluid state, and the calcium carbide formed by the action of the arc on the calcareous slag, are especially advantageous for desulphurisation. (3) The violent motion of the steel, which results from the convection currents produced in the bath due to the two intensely hot areas caused by the arcs below the electrodes, increases the volume of steel exposed to the hot and fluid slag area, and hence the rate of refining.

The usual procedure for the use of the electric furnace in connection with the Bessemer converter is to charge the steel, holding back all slag in the ladle, after putting on the bottom of the furnace, lime and mill scale or iron ore. This produces an oxidising or dephosphorising slag, which may be carefully skimmed or poured off. On the bath of steel, carbon is thrown to carburise to any required degree, and then a second highly basic and desulphurising slag is added. The arc acting on the calcareous slag produces calcium carbide, which may combine with sulphur to form calcium sulphide. As neither gases nor air enter the furnace, and the conditions are almost completely reducing, no sulphates are formed, a dead melt is easily obtained, and when the slag is molten and the requisite heat obtained, the steel is teemed. In the open-hearth or any oxidising furnace these reactions cannot take place so completely and efficiently.

With steel from the basic open-hearth furnace, the procedure is similar, but when the quantity of phosphorus to be removed is small, it is only necessary to use one refining slag for the elimination of sulphur and any small amount of phosphorus remaining. The usual practice is to put the carbon necessary for carburising in the bottom of the furnace and then add the steel and the basic slag materials. As soon as the teeming heat is obtained, the necessary ferro-alloys are added and the steel will be completely refined.

Another point of interest is the rarity of blow-holes in electric steel when properly made, and this leads to the question of the cause of these troubles. It is well known that any ingot of steel when placed in a vacuum evolves nitrogen, and this is about equally true whether it be made in the crucible, the Bessemer converter, or the electric furnace. Blow-holes contain nitrogen, but this is probably not the cause. It is far more probable that they are due to the combination of oxides with the carbon in the process of cooling, and that the carbon monoxide so formed at a high temperature causes blow-holes in the cooling steel, and owing to the diminution of volume of the carbon monoxide on cooling, a partial vacuum is formed, and nitrogen is sucked into the blow-holes. In electric steel, oxides do not occur in any quantity, and consequently the prime cause of blow-holes is reduced. Again, the quality of electrically refined steel is better than a material of similar chemical composition made in any oxidising furnace. This is probably due to the reducing conditions under which it is finished.

It must not be forgotten in discussing these special qualities of electrically refined steel, that some inferior material has been made by incompetent melters or in ineffective furnaces, and that the electric, just as much as any other furnace, requires trained men, and most careful designing by metallurgists who have made a special study and had practical experience in this subject.

The question of the cost of applying this process, which must be considered before all others, is more difficult to discuss generally, owing to the great variety of conditions. The following are the chief points, all of which must be carefully considered in each particular case: (1) The possibility of saving in cost of raw materials, since the best qualities of steel can be made from impure raw materials. (2)

* Paper (somewhat abbreviated) read before the Iron and Steel Institute, at Buxton.

Digitized by Google

Possibility of increasing the output of present furnaces by the addition of electric furnaces with improvement of product. (3) The cost of power and possibility of using blast-furnace or coke-oven gas, exhaust steam, &c., will be the determining factor in regard to deciding whether, in the manufacture of steel, electric refining can be economically adopted. In the case of cheap power or valuable products, scrap may be economically melted and refined in the electric furnace at a current consumption of 700 to 800 kw.-hours per ton, or if the price of power be high, the steel may be merely desulphurised and deoxidised, after melting and dephosphorising in a basic furnace, with a power consumption of 100 to 150 kw.-hours per ton. (4) The possible reduction of capital expenditure at certain works where the present products are not sufficiently good for modern specifications.

The figures given apply chiefly to Héroult furnaces, as this type has been far more widely adopted, and is used in larger units than any other. This furnace is similar to a basic open-hearth furnace, and seems to present more simplicity and to embody more of the desirable features of electric furnace design than any other. These features, in the author's opinion, are: (1) The best basic open-hearth design should be followed as closely as possible. A bottom homogeneous and solid and banks free from embedded electrodes is important, and above all simplicity of design. (2) All electric mechanism, in the form of generators, transformers, &c., should be entirely separate from the furnace, and should be of standard design. (3) A high-power factor must be maintained. (4) To avoid excessive cost of refractory materials, the roof should be protected from the direct radiation of the arcs by the electrodes themselves, and the intensely heated area of slag should be as large as possible, to increase the surface of refining action. (5) The heat should be applied to the slag as in the basic open-hearth furnace, and the temperature of the slag should be maintained above that of the steel, which allows of extreme basicity and fluidity being obtained and gives an intensely active refining action. The conditions in the furnace should be oxidising, neutral or reducing, at will.

The adoption of electric refining will cause some readjustment in the steel trade. As soon as the Sheffield steel melter has become acquainted with the process, and accustomed to the working of electric furnaces, electrically refined steel will largely replace ordinary crucible steel. This has already occurred in Germany and America. Large crucible plants and small open-hearth furnaces engaged in the manufacture of small and intricate castings, such as motor car parts, &c., may be replaced by electric furnaces, because the high degree of fluidity and dead melt obtained are especially advantageous. In many cases manufacturers of axles, guns and tubes will abandon the use of Swedish raw materials, and refine steel made from low-grade ores, thus reducing the value of high-grade ore deposits and the quantity imported; for, by the use of electricity, Cleveland stone will produce a steel equal to the best hæmatite ores. The capacity of many Talbot and basic open-hearth plants will be increased and the quality of the product improved, while much of the power that is now going to waste will be utilised for steel refining.

From the electrical engineer's point of view, the electric furnace is an attractive load, as it is more or less in continuous operation. In the case of the Héroult furnace the power factor is 0·88 to 0·90, though much less with large induction furnaces. Single, two or three phase current of any frequency from 20 to 60 has been used without any difficulty, though it is preferable in the case of a two-phase system to transform to three-phase current, which can be done without additional difficulty or expense. The load factor will be most favourable, the usual practice when refining, for example, in a 15-ton furnace, being to use 2,000 kw. for 20 minutes after charging, while the steel is being heated. The current is then reduced to about 1,500 kw. for 45 to 75 minutes until the steel is ready for teeming. There is then an interval of 10 to 15 minutes during which the furnace is teemed, fettled and charged, which allows the transformers or generators time to cool before the period of overload commences. Current fluctuations occur for a few minutes, while there is an evolution of gas from the steel which makes the bath boil up and touch the electrodes. This, however, is not sufficient to be objectionable, provided that the electrical machinery is properly designed for the purpose, and the extent of these variations is not so great as in the case of many rolling-mills, the fluctuations in voltage being only about 3 per cent. in the South Chicago works, where a 2,000 kw. furnace has been working steadily since May, 1909.

DISCUSSION.

Mr. E. H. Saniter (Rotherham) said he believed in the future of the electric furnace in certain directions, but he thought its future would be damaged by the furnace being recommended for the making of comparatively cheap qualities of steel, because people would find that the steel was not sufficiently improved to pay for the extra cost. He agreed that rails were not likely to be generally manufactured from the electric furnace at present. Even under the special circumstances at South Chicago, he was inclined to doubt whether the process would be continued. He believed they turned out something like 2,000 tons of rails in 24 hours. It was time members had some more definite information on the subject of costs.

Mr. E. C. Ibbotson (Sheffield) said many of the points mentioned by the author applied equally to the induction furnace. It was a question whether the arc furnaces, with their intensely hot areas, would not seriously affect the high-carbon steels such as were produced in Sheffield. The question of scorching ingots, and of the control of heat, was very important for these classes of steel.

Mr. J. H. Heap (London) said they could not give a simple answer to the question of whether steel could be made better or cheaper in the electric furnace. The general answer was, probably, that the more coke or coal was used, as fuel only, the better did electric smelting compete with the other processes. In fine crucible steel they had an expenditure on coke, as fuel, of 60s. to 70s. per ton of steel produced. If they took the consumption of electricity as 800 kw.-hours per ton, it would cost them, at ½d. per unit, 33s. 4d., so that they had a great margin, which was only slightly reduced by the cost of electrodes, &c. At the other end of the scale, for pig-iron they had a consumption of 2,000 kw.-hours per ton, costing nearly 84s., and this only represented a part of the coke, because they must still use the latter as a reducing agent. Between these two extremes there were intermediate stages at which the electric furnace could be economically introduced. In considering its application in place of crucibles, they must remember that they were limiting it to the conditions of the crucibles, and assuming that it would be working with the same pure materials; whereas, when they came to review the question all round, they recognised that it could start with cheaper material. An obvious application for the furnace was that of refining common Bessemer steel. In view of the importance of the subject of the electric furnace, he suggested that it should be officially considered by the Institute.

Mr. T. Rowlands (Sheffield) said it would be more correct to state that the South Chicago works were experimenting with the Héroult furnace than that they had adopted it. He wished for information as to the cost of electrodes for the large-sized furnaces. He understood that there had been considerable trouble with the carbon electrodes, and that graphite electrodes, costing 7½d. or 8d. a pound were being used.

Mr. F. W. Harbord (London) said that, from an economical point of view, the electric furnace could easily compete with the crucible. The next question was whether the quality of the product was equal, and he thought it must now be admitted that for practical purposes it was so. There might be some very special classes of steel which could only be produced from very carefully selected materials melted in a crucible, but for 90 per cent. of the purposes for which tool steel was required, electric steel, made by any of the well-known furnaces, met all the conditions. In the making of axles and tyres, too, there was a great opening for the electric furnace. It was useful in the making of moderately high-priced materials, very low in sulphur and phosphorus, but he did not think that, generally speaking, it could be applied to rail steel.

Mr. Campbell, in reply, said the making of rail steel at South Chicago might certainly be regarded as experimental. The work started in May, 1909, and several thousand tons of rails were made for the New York, Central Railroad, but until they had had a year's test it could not be decided whether the electric furnace should be used on a very large scale or not. In the meantime, it was being used chiefly for axles, tyres and castings with very satisfactory results. As to whether the electric furnace would displace the crucible furnace entirely, he said "No." He quite agreed that there were special cases where crucible steel would always hold its own, but there was a lot of steel made in Sheffield that could advantageously be made in the electric furnace.

THREE-PHASE ARC LAMP WITH FOUR CARBONS.*

BY ALDO RIGHI.

Before describing his particular design the author makes reference to the simple type proposed by the Edison Co. of Milan, in which three carbons—one connected to each phase—are arranged vertically with the arc underneath. The arc is maintained in this position due to the electro-dynamic action of the current. Experiments have also been carried out by R. Flemming, of Swampscott (Mass.), on lamps with six vertical carbons, the three top ones being each connected to a phase and the bottom three to the middle point of a star-wound transformer.

Mr. Mercanton, of Geneva, has constructed a lamp in which the carbons formed the edges of a regular trihedron, and moved in channels cut in a cone of refractory material. The circuits were Δ connected, and the regulation was effected by means of a differential three-phase motor.

Mr. Mercanton has closely investigated the efficiency of a lamp of this kind, using hand feeding for convenience, although a suitable mechanical regulator was devised by Bentivoglio & Siciliani, of Milan on the principle of two rotating fields in opposite directions.

With yellow flame carbons, 8 mm. diameter, and a current of

* Abstract of a Paper in the *Proc.* Assoc. Elettro. Italiana.

Digitized by Google D

20 amperes per phase at 38 volts and 38·5 ∞, the efficiency was found to be 0·16 watt per Hefner candle vertically and 0·217 horizontally. With plain carbons and a current of 15·17 amperes at 51 volts and 51 ∞, the corresponding figures are 0·192 and 0·58, whereas the ordinary monophase lamp has an average value of only 0·8 watt per Hefner candle-power.

Although the efficiency is relatively so high these lamps have scarcely come into practical use, probably because, as pointed out by Blondel at the Marseilles Congress in 1908, their candle-power is too high if they are to be stable, and also because it frequently happens that one of the arcs remains extinguished for a whole alternation. Due to this, the character of the light fluctuates more than would be expected, considering that at any instant there are always two arcs alight.

The new arrangement of carbons proposed by the author is the following. The three bottom carbons, of 8 mm. diameter, connected to each phase and adapted for fixing in the ordinary holder of a monophase lamp, are set vertically, so that they form the edges of a triangular prism, whose side measures 14 mm. to 15 mm. The fourth carbon, about 25 mm. diameter, is set above them co-axially with the prism, and is suspended in such a manner that it can deviate slightly from the vertical, so as to enable it to make simultaneous contact with the three bottom carbons.

In this way three star-connected arcs are formed with the production of six craters, which, as is well-known, are the main sources of luminosity in an arc lamp. Owing to the position of the three top craters the light is in great part thrown downwards without the necessity for using reflectors such as monophase lamps require.

The supply pressure can be adjusted either by impedances, or by transformers, mesh or star wound. In the latter case the fourth carbon can be connected to the centre point of the star. In the regulating mechanism the series coil carries the current of one phase, while the shunt coil may be connected between the fourth carbon and any one phase or between two phases. For the following experiments hand regulation was employed.

When the arcs are started between the three carbons, the fourth carbon, which at first is supported quite clear of them, is gradually lowered until it forms part of the path of the arcs and three craters are then developed in it.

During the movement there is not much change in the value of the current or the light emitted, but when the craters are once formed there is a marked diminution of the current, and the light, which to begin with, was fluctuating and badly distributed, undergoes a substantial increase, and gives a distribution which is well suited for illuminating purposes.

The author is unable to say *a priori* whether his arrangement should give a higher luminous efficiency than that of other three-phase lamps. He is content to emphasize the point that the increase in the number of craters (as was indeed to be anticipated) improves the efficiency.

He mentions another fact, which he is still investigating, and that is the very small consumption of the top carbon. In certain special conditions, instead of the craters, highly luminous prominences are formed extending towards the lower carbons.

The minimum frequency with which these lamps will work is an important point. In Mercanton's lamp as low a figure as 17 ∞ is possible, which can be explained by the close proximity of the three craters and the fact that at a given instant at least two of the arcs are alight, both causes preventing the cooling of the carbon points. In the author's arrangement it is hoped that lower working frequencies will be attainable on account of the great concentration of heat with the six craters.

The practical interest in this subject will be recognised, at least for conditions in Italy, on account of the numerous three-phase traction installations which run at 15 ∞ in that country. Arc lamps are at present debarred, as the monophase type will not work below 25 ∞.

The author hopes to return to the subject at a later date, more especially to determine the minimum possible frequency, and to give comparative figures for the luminous efficiency.

An Electrically-worked Passenger Counter.—According to the "Electric Railway Journal" a new mechanical device for registering the number of passengers as they pass into the McAdoo Hudson River tunnels is being installed for trial at the Hoboken, N.J., station. By interrupting a stream of compressed air, which holds an electric circuit open in an instrument across the passageway, each person completes the circuit and is registered. If this instrument continues to work successfully it may do away with the ticket checker.

HYSTERESIS LOOPS AND LISSAJOUS' FIGURES, AND THE ENERGY WASTED IN A HYSTERESIS LOOP.*

BY PROF. SILVANUS P. THOMPSON, D.SC., F.R.S.

Summary.—The author shows that any hysteresis loop can be analysed into a harmonic series of closed curves corresponding to the various terms in the analysis of the current wave. These constituents are examined in the Paper. Details are given of the analysis of various loops; the effect of eddy currents on the size and form of the loops is discussed, and an account is given of the effect of the higher sine and cosine constituents of the current wave.

Probably many physicists have attempted to find an explanation of the forms of the looped curves which express the hysteresis exhibited by iron and steel when subjected to cycles of magnetisation. Physical explanations to account for their general shape have indeed been given by Ewing and by Hopkinson. Neither of these pioneers, however, offered any mathematical equations to express their forms; nor, so far as appears, has any other person yet found any, though M. Pierre Weiss has put forward an electronic theory to account for the principal features. According to Ewing's molecular hypothesis of magnetism, the act of magnetisation consists in the orientation into a common direction of the axes of the elementary magnets constituted by the iron molecules which, when the mass of iron is in the unmagnetised state, are miscellaneous in their directions, the molecules being then arranged in groups within which the individuals are so oriented as to satisfy amongst themselves their various polarities in a more or less stable equilibrium. To deduce from this hypothesis an expression for the ascending curve of magnetisation, it might be possible to apply the statistical method, under the assumption that the number and variety of the groupings is enormously great. The ratio $d\mathfrak{B}/d\mathfrak{H}$ would represent at each stage the differential permeability of the specimen, or the rate (per unit of magnetising force) at which the magnetisation was proceeding; and this would at every stage be proportional to the probable number of groups that were coming into alignment, and to the magnitude of the aligning force. The expression would thus assume the form

$$\frac{d\mathfrak{B}}{d\mathfrak{H}} = a \cdot \epsilon^{-(\mathfrak{H}-b)^2},$$

where a and b are constants, the one denoting the maximum value of $d\mathfrak{B}/d\mathfrak{H}$, the other the particular value of $\mathfrak{H}$ at which that maximum is reached. The difficulty of integrating this expression is not the only objection to it; for it would at best give only the ascending curve of magnetisation, and additional assumptions would need to be made before it could be adapted to express the descending branch.

Hysteresis loops, as found by experiment, can, however, be considered from a wholly different standpoint. Whatever the law connecting $\mathfrak{B}$ and $\mathfrak{H}$, the area enclosed by the loop measures the amount of energy lost in the iron in the cycle of magnetic operations, the value, in ergs per cubic centimetre, being $\frac{1}{4\pi}\int \mathfrak{B} \cdot d\mathfrak{H}$.

Let it be assumed that the variations of $\mathfrak{H}$ are such that $\mathfrak{B}$ passes from the value $+\mathfrak{B}_1$ to $-\mathfrak{B}_1$ and back, through a regular cycle of values according to the expression $\mathfrak{B} = \mathfrak{B}_1 \cos\theta$; then, in general, the variations of $\mathfrak{H}$, though they go through a cycle, will not be capable of being expressed by any such simple form, otherwise the shape of the hysteresis loop would be simply an ellipse or, in the limiting case, a straight line. The fact that the magnetising current (and therefore the magnetising force) in choking coils and transformers does not follow a simple sine or cosine function is well known to all electrical engineers. In these instruments, if worked from a source of alternating E.M.F. in which the wave form of the supply is a pure sine curve, the wave form of the flux in the core, and therefore of the flux density $\mathfrak{B}$ in the core, will also be a pure sine curve having a lag of exactly 90 deg. with respect to the impressed voltage curve. Or if the impressed voltage is expressed by the equation $V = V_0 \sin\theta$, the flux density will be given by the equation $\mathfrak{B} = -\mathfrak{B}_0 \cos\theta$. But the current will not be capable of being expressed in any such simple fashion.† It has also long been known how these curves of magnetising current are related to the hysteresis loop. If the form of the hysteresis loop is known, then the form of the magnetising current can be deduced graphically. An example will be found in Kapp's "Transformers" (1908), Fig. 56, p. 106. Assuming that the flux density follows the equation given above, let

* Abstract of a Paper read before the Physical Society. A short account of the discussion on this Paper appeared in THE ELECTRICIAN, August 12, 1910, p. 735.

† These irregular current curves seem to have been first observed by Ryan, see "Transactions" of the American Institute of Electrical Engineers, Vol. III., January 10, 1890. *See also* THE ELECTRICIAN, Vol. XXIV., p. 239 and p. 263, January, 1890, and Vol. XXV., p. 312, July 25, 1890.

Digitized by Google

it be plotted as a curve, with maximum ordinate equal to that of the hysteresis loop. Consider any point on this curve, or the point on the loop having the same ordinate; then the ordinate at the same instant on the current curve will be (on some scale) proportionate to the abscissa of the same point of the hysteresis loop; whence it follows that the current curve can be constructed, point by point, through the entire cycle. This process is followed here, save that for convenience the hysteresis loop is turned over through a right angle, so that the values of B are taken as abscissæ, and those of H as ordinates.

In Fig. 1 the hysteresis loop ABCDEF selected has been taken from Ewing's classical memoir of 1885. Assuming a closed magnetic circuit, and an impressed voltage of a pure sine form, marked V, the flux density curve is a sine curve lagging 90 deg. behind the voltage curve. Then the current curve is derived by taking any point P on the hysteresis loop, projecting it by first turning its abscissa through a quadrant about the centre O, then tracing along horizontally to the point Q on the flux density curve, where a vertical line, QM, is dropped. Then a horizontal line projected from P cuts QM in R, giving thus the corresponding point on the current curve, the peak of which, corresponding to the cusp of the loop, occurs at the time when the flux density curve is a maximum, and when the voltage curve is at its zero. It will be seen that the wave form of the current curve reflects, in a certain way, the form of the hysteresis loop. If the loop is sharply cusped, the wave curve will have corresponding sharp peaks. In fact, the loop consists of the two halves of the wave curve, folded back one upon another, but with the ordinates differently spaced, exactly as if the wave curve had been wrapped around a cylinder* and projected upon a plane cutting the cylinder diametrically through the two peaks of the curve.

Now this current curve can be subjected to harmonic analysis, and its harmonic constituents discovered. Each constituent will be a pure sine curve or cosine curve. If each such constituent be drawn, and then be projected back by reversal of the process by which the wave curve was obtained, the several constituents will

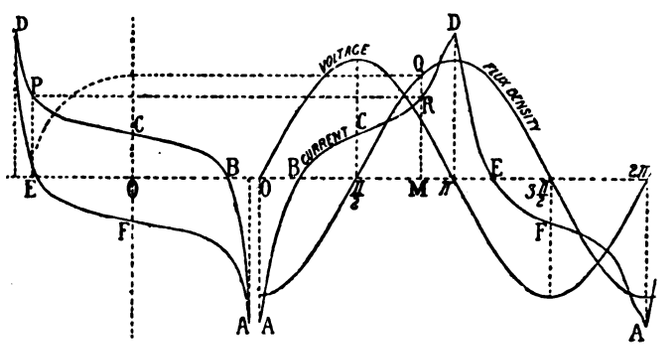

FIG. 1.—RELATION OF CURRENT CURVE TO HYSTERESIS.

reappear as separate closed curves; and by the summation of these the original hysteresis loop can be reconstituted. It thus appears that *any hysteresis loop can be analysed into an harmonic series of closed curves corresponding to the various terms in the analysis of the current wave.* An examination of these constituents of the hysteresis loop is the principal object of this communication.

In this graphic process, which is equivalent to wrapping the periodic curve around a cylinder, the area of the projected curve is equal to the integral, over the whole period, of products obtained by multiplying each ordinate by the sine of the angle at which it stands in the wave curve, abscissæ in that curve being reckoned as values of angles. (The origin of the cycle is taken where the curve has its negative peak.) In symbols this is equivalent to $\int_0^{2\pi} \sin\theta \,.\, \psi(\theta) \,.\, d\theta$. Now $\psi(\theta)$, the function which represents the current curve, may by Fourier's theorem be expanded into the series

$$A_1 \sin\theta + A_3 \sin 3\theta + A_5 \sin 5\theta + \ldots A_n \sin n\theta + B_1 \cos\theta + B_3 \cos 3\theta + B_5 \cos 5\theta + \ldots B_n \cos n\theta.$$

Odd terms only are present, as in all alternating current work; and there is no constant term, because the mean ordinate is already zero. The constituent terms in the area of the hysteresis loop correspond therefore to the integrated products of $\sin\theta$ into the successive terms of the above series.

To investigate the form of the constituent elements of the loop, let us consider a simple harmonic motion $x = X \sin\theta$, where θ stands for $2\pi ft$, f being the fundamental frequency and X the amplitude.

* As in the graphic method of harmonic analysis of Clifford described by Perry in "Proc." Phys. Soc., Vol. XIII.

This motion is to be compounded, at right angles, with another simple harmonic motion $y = Y_n \sin(n\theta + \phi_n)$, where Y_n is the amplitude, ϕ_n a possible angle of phase-difference, and n any (odd) integer giving the order of the harmonic. We have then to find an expression for the curve of which x and y are the co-ordinates. For simplicity we deduce the expressions where $n=1$, $n=3$, and $n=5$, that is for the first, third and fifth terms of the constituent elements.

First Term (Fundamental); $n=1$. We have

$$x/X = \sin\theta. \quad \ldots \quad (1)$$
$$y/Y_1 = \sin(\theta + \phi_1). \quad \ldots \quad (2)$$

Multiplying both sides of (1) by $\cos\phi_1$, we have

$x/X \cos\phi_1 = \sin\theta \,.\, \cos\phi_1$; also $y/Y_1 = \sin\theta \,.\, \cos\phi_1 + \cos\theta \,.\, \sin\phi_1$.

Subtracting this equation from the preceding, we have

$$x/X \cos\phi_1 - y/Y = -\cos\theta \,.\, \sin\phi_1. \quad \ldots \quad (3)$$

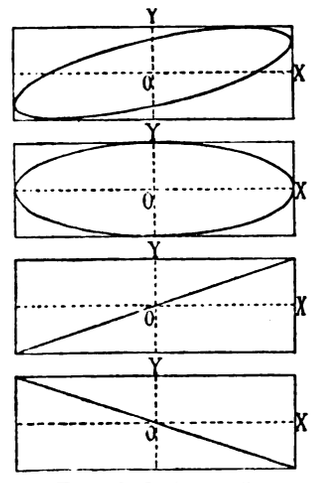
Multiplying (1) by $\sin\phi_1$, we get

$$x/X \sin\phi_1 = \sin\theta \,.\, \sin\phi_1. \quad \ldots \quad (4)$$

Squaring (3) and (4) and adding them gives us

$$\left(\frac{x}{X}\right)^2 + \left(\frac{y}{Y_1}\right)^2 - 2\frac{xy}{XY_1}\cos\phi_1 = \sin^2\phi_1. \quad \ldots \quad (5)$$

This is the equation to an ellipse, such as is represented by Fig. 2. According to the values given to ϕ_1 there arise three principal cases: (i.) If $\phi_1 = \frac{\pi}{2}$ or $3\frac{\pi}{2}$, the equation becomes $\frac{x^2}{X^2} + \frac{y^2}{Y_1^2} = 1$, an ellipse set orthogonally with respect to the co-ordinate axes (Fig. 3). (ii.) If $\phi_1 = 0$ the equation becomes $\frac{x^2}{X^2} + \frac{y^2}{Y_1^2} - 2\frac{xy}{XY_1} = 0$, whence $y = +\frac{Y_1}{X}x$, and the ellipse shrinks into a straight line as in Fig. 4. But its



FIGS. 2, 3, 4 AND 5.

length is limited by the prior expressions, since x and y cannot exceed X and Y_1 respectively. (iii.) If $\phi_1 = \pi$, the equation becomes $\frac{x^2}{X^2} + \frac{y^2}{Y_1^2} + 2\frac{xy}{XY_1} = 0$, or $y = -\frac{Y_1}{X}x$, which is a straight line sloping the reverse way as in Fig. 5.

For all other values of ϕ the ellipse takes some intermediate form. The sine-component of the first term in the harmonic analysis of the current curve corresponds to the orthogonal ellipse; the cosine-component to the oblique line form. All the intermediate forms of the ellipse could be obtained by wrapping a sine-curve of period T around a cylinder of diameter T/π and projecting in appropriate directions upon planes parallel to the axis of the cylinder the apparent outline of the sine-curve.

Third Term (Third Harmonic); $n=3$. Here the two equations are $x/X = \sin\theta$ and $y/Y_3 = \sin(3\theta + \phi_3)$. From these the author obtains the equation

$$\left(\frac{3x}{X} - \frac{4x^3}{X^3}\right)^2 + \left(\frac{y}{Y_3}\right)^2 - 2\left(\frac{3x}{X} - \frac{4x^3}{X^3}\right)\frac{y}{Y_3}\cos\phi_3 = \sin^2\phi_3,$$

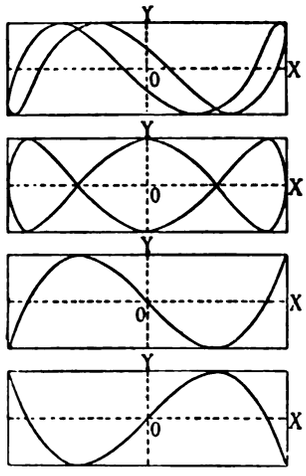
which is the equation to a figure having the general form of Fig. 6, the well-known Lissajous' figure, compounded of two vibrations the frequencies of which are as 1 : 3. It could be obtained by taking three complete sine-waves, each of period T/3, and wrapping them around a cylinder of diameter T/π. Again there arise three cases:— (i.) $\phi_3 = \frac{1}{2}\pi$ or $\frac{3}{2}\pi$. (ii.) $\phi_3 = 0$ and $\phi_3 = \pi$. The corresponding curves are shown in Figs. 7, 8 and 9.

Fifth Term (Fifth Harmonic); $n=5$. The two equations now are $x/X = \sin\theta$ and $x/Y_5 = \sin(5\theta + \phi_5)$. From these the author obtains

$$\left(\frac{5x}{X} - \frac{20x^3}{X^3} + \frac{16x^5}{X^5}\right)^2 + \left(\frac{y}{Y_5}\right)^2 - 2\left(\frac{5x}{X} - \frac{20x^3}{X^3} + \frac{16x^5}{X^5}\right)\frac{y}{Y_5}\cos\phi_5 = \sin^2\phi_5.$$

Digitized by Google

This is the equation of the general Lissajous' figure of the fifth order, representing the result of compounding two vibrations having relative frequencies of 1 : 5, and a general form like Fig. 10. As before, three cases arise: (i.) $\phi_5 = \frac{1}{2}\pi$ or $\frac{3}{2}\pi$. (ii.) $\phi_5 = 0$. (iii.) $\phi_5 = \pi$. The corresponding curves are shown in Figs. 11, 12 and 13.



FIGS. 6, 7, 8 AND 9.

The Higher Terms (generalised expression for the Lissajous' Curve of the nth term).—The expression for any higher term has the general form

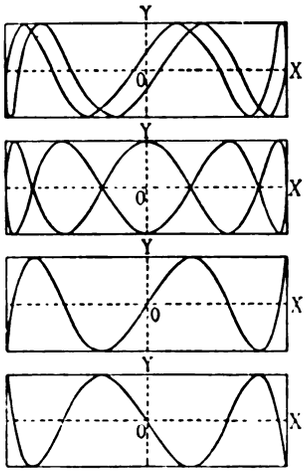
$$G_n^2 + \left(\frac{y}{Y_n}\right)^2 - 2G_n\frac{y}{Y_n} \cdot \cos\phi^n = \sin^2\phi_n,$$

which reduces in the case of symmetry to $G_n^2 + \left(\frac{y}{Y_n}\right)^2 = 1$, and, in cases where $\phi_n = 0$, to $G_n \pm \frac{y}{Y_n} = 0$, in which expressions G_n is written for the series

$$G_n = n\frac{x}{X} - C_3\frac{x^3}{X_3} + C_5\frac{x^5}{X^5} - C_7\frac{x^7}{X^7} + \ldots + C_n(-1)^{\frac{n-1}{2}} \cdot \frac{x^n}{X^n},$$

where $C_r = \frac{n(n^2-1^2)(n^2-3^2)\ldots\ldots(n^2-r-2^2)}{\lfloor r}$, where r is an odd number greater than unity.

It is now possible to re-state the proposition italicised earlier in the Paper in the following way. *Any hysteresis loop can be analysed into an harmonic series of Lissajous' figures* of the kind just considered.



FIGS. 10, 11, 12 AND 13.

A number of examples of hysteresis loops were chosen, and subjected to harmonic analysis, to ascertain what constituents were present. The loops chosen relate to various kinds of iron and steel, hard and soft, solid and laminated, taken by various methods; a wide selection being made in order to ascertain the physical significance of the several constituent terms. In carrying out the analysis the author used the simple approximate method described by him to the Physical Society, December 9, 1904. It was found that for the present purpose it sufficed to ascertain the harmonic sine and cosine terms up to the eleventh, and therefore to employ 12 equidistant ordinates in the half-period. At first the values of the 12 ordinates required for the analysis were taken from the current curve plotted, as explained above, from the hysteresis loop. But it was seen that it was unnecessary to draw the current curve, and that the values of the ordinates might be taken direct from the hysteresis curve, by taking them not equidistant, but at places corresponding to equidistant points in the axis of abscissæ of the wave curve, which points, when the curve is wrapped round a cylinder, will no longer appear equidistant.

Fig. 14 shows one of the several results given by the author. The example is Ewing's loop for annealed iron wire, being Fig. 5 of Plate LVIII. of "Phil. Trans." 1885. The analysis gives:—

Sine terms.	Cosine terms.
$A_1 = 3{\cdot}98$	$B_1 = -7{\cdot}38$
$A_3 = 2{\cdot}14$	$B_3 = -4{\cdot}74$
$A_5 = 1{\cdot}36$	$B_5 = -2{\cdot}04$
$A_7 = 0{\cdot}88$	$B_7 = -3{\cdot}78$
$A_9 = 0{\cdot}16$	$B_9 = -2{\cdot}14$
$A_{11} = 0{\cdot}14$	$B_{11} = -1{\cdot}90$

The ellipse and the straight line, corresponding respectively to A_1 and B_1, have been added in dotted lines in the figure.

Work done in the Cycle.—It was early pointed out by Warburg and by Ewing that the work spent in carrying the iron through a cycle of magnetising operations was represented by the area of the hysteresis loop. We now consider this from another point of view. Whatever work is spent in magnetising the iron is derived from the electric energy which is imparted by the circuit, and this, at any

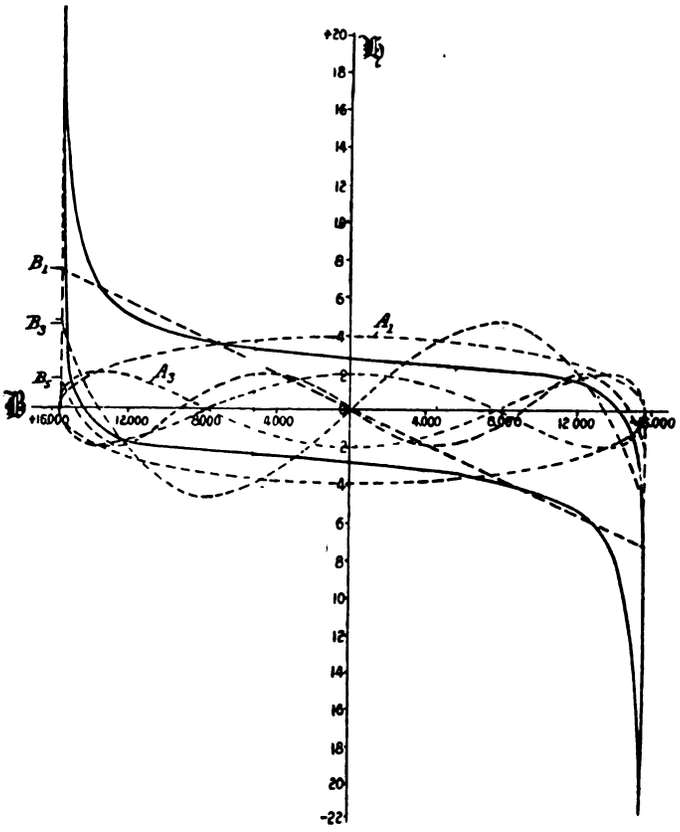


FIG. 14.

instant, is proportional to the product of the current and potential at that instant. If the voltage is represented by the expression $V = V_0 \sin pt$, where p stands for $2\pi f$, and if the current, being some periodic function of the time, is represented as $C = \psi(pt)$, then the element of work imparted to the circuit during time dt being $CV dt$, the work given to the iron (if the copper resistance is negligible) during one cycle will be

$$V_0 \int_0^T \sin pt \cdot \psi(pt) \cdot dt.$$

But $\psi(pt)$ consists (see above) of a series of harmonic sine and cosine terms. The quantities which will be formed by multiplying the members of that series by $\sin pt$, and integrating each product over a whole period, will fall under three kinds, the values of which are known, viz.:—

(i.) $\int_0^T \sin pt \cdot A_n \sin npt \cdot dt = 0$ (except when $n = 1$);

(ii.) $\int_0^T \sin pt \cdot B_n \cos npt \cdot dt = 0$ (in all cases);

(iii.) $\int_0^T A_1 \cdot \sin^2 pt \cdot dt = A_1 \cdot \frac{T}{2}$.

Digitized by Google

That is, *the only work done in the cycle* is that done by that constituent of the current which is in phase with the voltage, namely, its fundamental sine term. *All other constituents are wattless.* And since the area of the loop represents the work done, it follows that the area of the hysteresis loop is equal to the area of the orthogonal ellipse which is its fundamental constituent of the sine series. *The true and fundamental form of every hysteresis loop is therefore an orthogonally placed ellipse.* All departures from that form are wattless—are mere distortions which involve no expenditure of energy. The area of the hysteresis loop is proportional to the maximum value of $\mathfrak{B}$ and to the amplitude of the first sine term into which the values of $\mathfrak{H}$ (corresponding to the values of the current) can be analysed. If the value of the amplitude of that sine-term be denoted by $\mathfrak{H}_1$, then the area of the loop is accurately given by the expression $\frac{\pi}{4} \times \mathfrak{B}_{max.} \times \mathfrak{H}_1$, being the area of the fundamental elliptical constituent.

Presence of Eddy Currents.—If the hysteresis loop has been produced by some slow process, absence of eddy currents may be assumed. But this is by no means the case when alternating currents of ordinary frequencies are used, even if the iron be finely laminated. It therefore remains to be seen how the presence of eddy currents will affect the size and form of the hysteresis loop. The eddy current, being a secondary current, will be of pure sinusoidal form only if the inducing E.M.F. be of a pure sinusoidal form, and if the resistance and permeability be constant also. But it is not necessarily in phase with the impressed E.M.F., but may lag by magnetic reaction, and indeed, as is already known, lags by different amounts at different depths below the surface of the iron. Assuming equal permeability and resistance in the different layers, the effect of the eddy current will be represented with sufficient accuracy by a sine-curve lagging by an amount that will depend on conditions into which there is no need here to enter. For

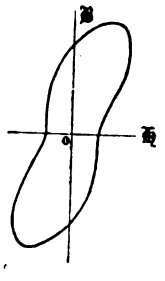

Fig. 15.

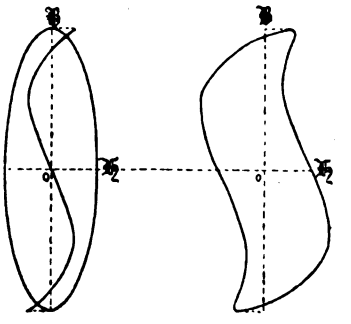

Fig. 16.

here, again, the only effective component—effective, that is, in the sense of involving expenditure of energy—is the sine-component in phase with the voltage, and the element which the sine-component contributes to the loop is an orthogonal ellipse. So far as it lags it possesses a cosine-component, and this contributes to the loop only an oblique line, shearing the loop over; but this constituent is wattless. Harmonic analysis cannot of itself distinguish as to how much of the fundamental elliptical constituent of the loop, or of the fundamental sine-component of the magnetising current, is due to eddy currents and how much to hysteresis. It is, indeed, already known* that the effect of eddy-currents is to widen out the loop elliptically.

Effect of the Higher Sine-Constituents.—The third harmonic has been noted above. Indeed, it is usually present. A fine example is afforded by the curve, Fig. 15, taken from Fleming's "Alternate Current Transformer." It is obvious that the effect of superposing a third-term sine-constituent upon the fundamental ellipse will be to narrow it at the middle. It will widen it towards the ends, the widening beginning at a distance of 0·134 of the semi-major axis from the ends. If sine-constituents were present, of all orders, in the following proportions, $A_1=1$, $A_3=\frac{1}{3}$, $A_5=\frac{1}{5}$ ..... $A_n=\frac{1}{n}$, the form of the loop would become a pure rectangle.

The half-width of any static hysteresis loop, which is commonly taken (following Hopkinson) as a measure of the coercive force, is independent of all the cosine terms, and is in all cases equal to $A_1-A_3+A_5-A_7+A_9-$, &c. For loops of equal height (that is, equal maxima of flux density) the coercive force is not proportional to the work spent in the cycle; for the work spent in the cycle is represented by the area of the loop, and, as shown above, this is invariably proportional to A_1, while the coercive force is represented by the sum of the series named in the previous sentence. Since in static hysteresis loops the fifth and higher terms are practically absent, the coercive force is proportional to A_1-A_3.

Effect of the Cosine-Constituents.—As already seen, the fundamental cosine-constituent is an oblique line. It is in reality a double line, traversed upwards during half the cycle, and downwards during the other half. The effect of superposing this constituent upon the fundamental ellipse is to shear it over. Cosine-components are always negative, corresponding to lagging constituents of the wave-curve. They shear the $\mathfrak{B}$-$\mathfrak{H}$ curve over toward the right, on the ascending side. If a mass of iron undergoing magnetisation is traversed by an air-gap, or is constituted as a non-closed magnetic

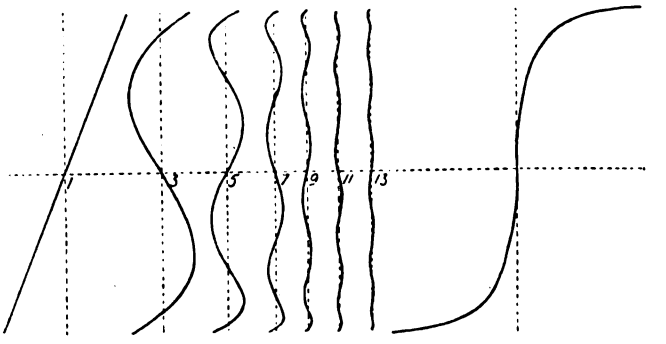

Fig. 17.

circuit, the reaction of the air-gap brings a lagging constituent into the magnetising current, imposing a negative cosine-constituent upon the loop, and shearing it over.

The presence of negative cosine constituents in hysteresis loops is specially marked in those beaked forms which are obtained when the magnetisation has been pushed to high degrees of saturation: the diminished permeability of the material resulting in a diminished reactance, and therefore in a disproportionate increase in the magnetising current. Fig. 16 shows the result of superposing a negative third cosine constituent upon the ellipse. But this particular figure, resembling a capital S, could not result from any experiment, as neither the ascending nor the descending half is single valued. Such a curve would be unstable; and the ascending branch could, at most, ascend parallel to the $\mathfrak{B}$ axis before turning

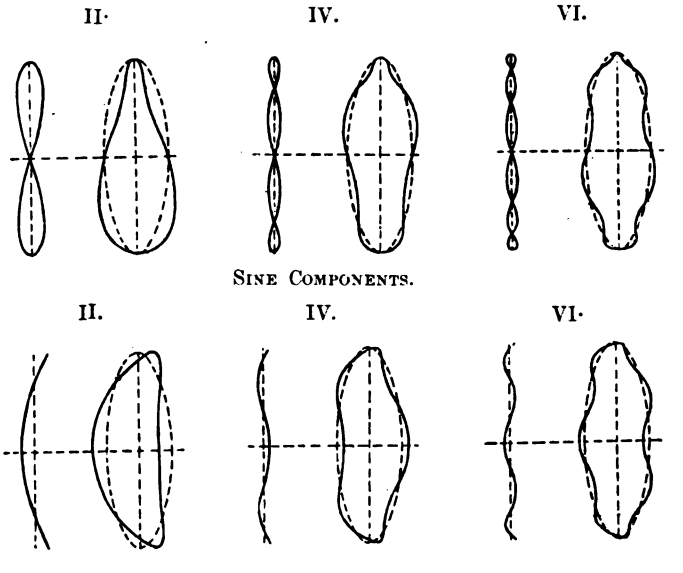

Fig. 18.

to the cusp. Is it too remote to speculate that the vertical portions of the loops experimentally found for soft iron really do represent instabilities, and mask the true forms of the loops?

It is noticed that in the analyses of some of the loops the amplitudes of the negative cosine terms appear in a descending set of values. If these amplitudes are of relative magnitudes as $1:\frac{1}{2}:\frac{1}{4}:\frac{1}{8}$, &c., the resultant curve will have its middle portion truly vertical. Fig. 17 gives a set of such curves up to the thirteenth order, together with their resultant. If this resultant is then superposed on a fundamental ellipse, the result is a characteristic two-beaked loop. The horizontal

Digitized by Google

length from the cusp to the vertical axis (*i.e.*, the amplitude of ϕ at its maximum) is in all cases equal to $B_1 + B_3 + B_5 + B_7$, &c.

Effect of Harmonic Constituents of Even Orders.—If constituents of even orders could exist, they would produce distortions of the loop, such as are shown in Fig. 18. No such distortions have ever been observed.

Hysteresis is commonly regarded as an irreversible process, and as such involving a degradation of energy into heat. But in view of the present analysis of the hysteresis loop it is necessary to revise this opinion. In the first place, no energy is wasted in producing any cosine component of the loop. In the case of the first cosine term—the oblique line—the distortion is a mere shear. True energy is spent in half the cycle in producing the magnetic flux, but that energy is returned to the magnetising circuit during the other half of the cycle, exactly as it is in the case of the production of a magnetic flux in a solenoid devoid of iron. The like is true of the higher cosine components. Also the sine components higher than the first represent reversible processes. The only component which represents an irreversible process is the fundamental sine component, the ellipse, itself due to that component of current which is in phase with the voltage. This irreversible part is due in detail to an energy waste which at every instant is proportional to the square of the magnetising current, and is in phase with it. True hysteresis waste accompanies the current, and does not either lag behind it or precede it. True hysteresis does not cause any lag in the current, being necessarily simultaneous with it. True, the curve of the flux density always lags 90 deg. behind the voltage curve, and therefore 90 deg. behind the effective component of the current curve. Of the reversible components, it is the first cosine term which is concerned in the lag of the current, and the lagging component of current is wattless. The higher cosine components conjointly produce additional lags, and are also wattless. The higher sine components, also wattless, do not cause any lag of the current as a whole. The name "hysteresis" was originally given* to the phenomenon to connote an effect which lagged behind its cause. The term is now usually restricted to the phenomenon of energy waste. But the energy waste does not involve or produce any phenomenon of lag. On the contrary, as it is a simultaneous phenomenon, its presence actually produces an advance in the phase of an otherwise lagging current. The greater the reluctance of the magnetic circuit, the greater the angle of lag. The less the permeability which enters into that reluctance the greater is the angle of lag. The lagging components, that is the cosine components of the loop, so far as they are not due to eddy currents, depend solely upon the reduction of the permeability of the iron during the process of the cycle of magnetisation. The lag is in fact due to components other than the fundamental component which represents the true hysteresis.

ELECTRIC RAILWAY CATENARY TROLLEY CONSTRUCTION.†

DISCUSSION.

Mr. P. H. Thomas asked as to the practicability of obtaining sparkless action in pantagraph trolleys by having a relatively light piece on the top of the pantagraph which would have the least possible inertia. The heavy arms would then not be required to follow every slight movement of the sliding contact.

Mr. C. J. Hixson said the vertical flexibility of the trolley wire seemed the keynote to the successful collection of the current. The general conditions of stability and of sidewise anchorage limited the vertical flexibility to a few inches, and it was necessary to assist this flexibility by frequent supports or hangers. The height of the wave in the trolley wire as the collector passed along should be such as to take up all the sag between hangers and still raise the hanger a couple of inches as it passed under it. The lifting of the hanger to a floating position eliminated the blow that would be delivered to a rigid support. Catenary hangers rigidly connected became increasingly hard as the bracket-arm was approached. With a flexible hanger the increased and ever present flexibility at the point of contact compensated in a measure for the inherent sluggishness of the roller pantagraph. For very heavy currents with two trolley wires side by side vertical flexibility was of great assistance in keeping the necessary contact pressure down to a modest figure and yet maintaining continuous contact with both wires at all times. In order to have vertical flexibility the strain in the trolley wire should be moderate, say, from 1,200 lb. to 1,500 lb. With this tension, with hangers 13 ft. apart and with a No. 4/0 trolley wire, a vertical flexibility of an inch or so could be attained with an upward pressure of about 7 lb. This low tension in the trolley reduced the strain upon pull-offs, anchorages, strain insulators, and the line in general, thereby decreasing the original cost and the cost of maintenance. The trolley wire was held best on curves by frequent pull-offs. This gave maximum flexibility with low stresses and moderately strong strain insulators. On earlier installations steady braces were used, but they had now been superseded either by flexible pull-offs or line steadiers. In conclusion, he mentioned thata single messenger flexible catenary had been in successful operation for the past two years upon the Saratoga division of the Schenectady Railway. There had been no sign of wearing the galvanising on the messenger wire due to the movement of the loop, as the sides of the same seldom if ever more than just touched the messenger wire.

Mr. R. D. Coombs considered that since the track on which the equipment ran was not a plane, but a series of vertical curves, it was entirely unnecessary to attempt to keep the trolley wire perfectly horizontal. The question of flexibility was as yet very uncertain. The Germans had used a secondary catenary, and according to their statement it was entirely successful, but their speeds and trainloads were less than in America. The experiments made by the Pennsylvania Tunnel & Terminal Railroad seemed to indicate that a single catenary with a very light hanger, composed of a flat section, 1⅛ in. by ¼ in., looped over the messenger, and with the ordinary type of ear, was about as successful during the limited range of those experiments, as the German type with the auxiliary catenary. He believed that a light hanger, particularly in conjunction with a trolley wire having considerable stiffness and strength, possibly a steel trolley wire, as used on part of the New Haven installation, with either a copper messenger or copper feed wire to provide the necessary conductivity, would be a combination worth very carefu investigation, and perhaps some experimentation. The little hanger which looped over the secondary wire and attached to the trolley wire permitted vertical movement, but seemed to have a tendency to roll. On a portion of the experimental line, in putting up the trolley wire it was found that the trolley wire had a twist or roll in it, and that the little hanger above the car rolled laterally and became, to a certain extent, bound, particularly at a pull-off. He doubted whether it was necessary to pull the trolley wire to an excessive tension; and he believed it to be a subject which required more investigation. The pantagraph had always seemed to him to be a suitable field for experiments, and he noted that the secondary flapper, according to the statements of the German engineers, had given entire satisfaction abroad. He had been told that their auxiliary arrangement on top of the pantagraph gave entire satisfaction and that it did not spark. Their speeds were less than in America, and their train-loads were also less; but if these pantagraphs had given the satisfaction abroad which it was claimed, it would certainly seem that the pantagraph was a field for further experimentation and improvement.

Mr. R. C. Thurston said that during a high wind and from the rolling of the car, unless the wires were in ideal condition, there was a good deal of slack wire, which would cause the trolley or the pantagraph to go on one side and dip, and while over, allow the ends of the shoe to hit the cross-arm. If the wire was perfectly tight this would not happen. When their road was first installed they had no such trouble, but after the heat of summer and the cold of winter had expanded and contracted the wire there was slack. But owing to the expense and the lack of time between trains, it was not always advisable to pull a slack wire tight. The spacing rods were clamped tight to the messenger wires. He believed there should be a loop at the top of the spacing rod to allow the spacing rod to slide along the messenger wire, as the slack in the trolley wire would not then form the kinks in the trolley wire that it did now. They had had several bad cases of breaks in the copper wire and the break was not sudden, but was found to be an old fracture, probably caused by the pounding of the shoe. As these breaks did not occur in cold weather, it showed they were not from contraction of the wire through cold. The break was always formed after the car had passed.

Mr. C. R. Harte thought it was too often forgotten that the overhead construction of an electric railroad served in two capacities: As a conductor its function was simple and well understood; that it was also the track upon which the collector travelled at high speed was too frequently ignored, although it was in this latter capacity that practically all of the serious problems and difficulties arose. Up to the present time developments had indicated that the flexible line was easier of attainment than the rigid type; the writer believed, however, that the possibilities of the rigid construction had been by no means exhausted, and he hoped to see further experiment in that direction. The unfavourable condition was that in which whatever the cause, the trolley wire tended to bend on a short radius. A truly straight trolley wire was by no means a necessity. It was not the amount of the intersection angle at directional changes, but rather the shortness of radius of the enclosed curve that caused injury. With a long radius bend, and a type of support which would either gradually damp out the displacement wave or would transmit it without material interference, a heavily sagged trolley ought to give excellent service under severest conditions. Such a type of suspension, employing spans of 240 ft. with a sag of 30 in., the wire being carried in a curved ear of special design, and some 44 in. long, had been proposed by Mr. J. Mayer, but so far as the writer was aware had never been actually tried out. The author, in describing double catenary construction, had said, "The excessive rigidity of this type has been found undesirable in practical operation." As an unconditional statement this was open to question. It was quite true that the first installation of this type to receive a thorough try-out was not entirely satisfactory, but the difficulty arose from the fact that while the hangers were very rigid, the line between yielded. At the critical speed the resultant chatter of the collector became synchronous with its period of vibration, and the line received severe punishment from the heavy blows of the pantagraph, in addition to the tendency to crystallisation from bend reversals. The difficulty was most successfully overcome by duplexing the trolley, attaching the lower wire to the old trolley only at the centres of the

† Discussion on a Paper read before the American Institute of Electrical Engineers. An abstract of this Paper was given in our issues of September 16th and 30th.

Digitized by Google

secondary spans, but it was at least open to question if equally good results would not have been obtained had the line been made uniformly rigid by the use of a tee or similar stiff section attached to the hangers. As pointed out by the author, the question of the side clearances of poles was very important on electrifications, and particularly so on railroads with block signals. 8 ft. from centre of track to face of pole brought the latter practically in line with the signal mast in its usual position, and the engineer or motorman was hedged by an apparently solid wall of poles, behind which except as it was very near, nothing could be seen. Certain types of signal employed a centrally pivoted blade, half being in front of the mast, to obviate this difficulty of sighting, but even for this 10 ft. clearance from track centre to face of pole was little enough. The author's conclusion that the trolley wire should very closely follow the centre line of the track would have the endorsement of practically all operating men, particularly if qualified by the further proposition that for wheel work the centre of the track was to be considered projected through the centre line of the car, in order to meet the offsetting of the wheel by the super elevation of the rail. This same offsetting affected the lengths of brackets on curves particularly if the poles were on the outside, in which case the bracket bar would often have to be materially longer than the standard. Operating men generally would further agree with the author that the irregular and unavoidable cross motion of the shoe, due to various car movements and sways, entirely obviated the necessity—and most undesirable complication—of staggering the trolley wire to prevent localised wear on the collector. To secure the desired alignment on curves, the preference of the writer was with the method by bridle between poles from which were taken equidistant pull-offs. The matter of proper tension in the wire was complicated by the fact that conditions preventing excessive sag at high temperature resulted in very high stresses at low temperatures. How closely these stresses might approach the actual breaking strength of the wire was not always realised. Grooved 4/0 copper trolley was usually credited by the handbooks with a breaking strength of from 8,000 lb. to 8,400 lb. A series of tests made by the writer, however, on commercial stock samples gave a maximum of barely 7,100 lb. on the unbrazed portion, with an average at brazes of 5,600 lb., two samples failing below 5,000 lb. While there were some differences as to detail, commercial trolley wire was in general made from a "wire bar" of rectangular section, which was first rolled down to a round rod and then finished by drawing. Brazing was usually done just before drawing, and in the samples tested it was evident that the latter treatment was not sufficient to overcome the local annealing at the surfaces of the braze. It was generally believed by users that trolley wire could with advantage receive further treatment than was at present usual, for the market material of to-day certainly had decidedly less resistance to wear than the earlier output. The writer was watching a working test of especially rolled wire which gave to 4/0 grooved copper an average breaking strength of practically 9,000 lb. But it was after all an illogical proceeding to impose the duty of resisting the abrasive action of the collector upon that member of the overhead which by nature was least adapted to resist wear, and functionally was most affected by loss of section, as was the case when the trolley wire was of copper. The author would doubtless be interested to know that his suggestion of a steel trolley and copper messenger had actually been in service for over a year. The trolley wire was identical in section with 4/0 grooved copper; the messenger was 19 strand bare copper wire cable sagged 24 in. for standard spans of 150 ft. This was on the experimental catenary section of the Connecticut Company's Hartford–Middletown line. At night the wheel had a bright tail of light, but the actual wear in over a year's service was inappreciable, and this was also true of the messenger where it was feared the loops of the sliding hangers might cut the copper. This latter would indicate less danger to galvanising on a steel messenger from sliding hangers than had been anticipated by some. The Connecticut Company's experimental catenary had not had long enough service for final deductions as to the most desirable type of hangers, but indications seemed to point to the old mechanical screw clamp ear with light hanger rod rigidly fastened to the ear and looped over the messenger. The screws should be long enough to head up after the trolley was gripped; if this was properly done the type was at least as efficient as the more elaborate forms and was far simpler. In this connection the author expressed a preference for "a nut screwing down on the lower end of the hanger rod." In the writer's experience, while the nut could not escape, it had been found necessary for such types of hangers to be fitted with a lock-nut, as otherwise the main nut backed up to the rod enough to loosen the clamp and permit serious wear. Rigid hangers required high trolley tension, and in case of relative movement of trolley and messenger were apt to come to grief; hinged types, if jointed top and bottom and rigidly gripped to messenger, allowed relative movement and gave a little flexibility that hardly seemed commensurate with the complication. Bottom slide hangers seemed unduly subject to wear, but had the marked advantage that the parts lifted were all of equal weight. The foreign sliding hanger lines had a secondary messenger of very slight sag and the loop hangers were all of equal length and weight; that satisfactory results were not obtained on certain American lines where hangers varied in length from 4 in. to 20 in. was hardly surprising. Long loop-hangers hinged at the ear had a tendency to tip when lifted, and sliding down the messenger lost their characteristic feature: and as a result of the shortened effective length, picked up the trolley. Hangers with jaws closing symmetrically with reference to the rod would, within the limits of their capacity, take various wire sizes equally well; hangers in which the jaws did not so move, however, while they had a small range, did not work well on sizes other than the one for which they were designed. For shoe work the contour of the jaws was of less importance; for wheel work it was essential that the jaws gave good clearance lines, or, particularly on curves, they would be badly pounded. The matter of hanger spacing was one on which was needed much practical information. It was the general impression that for shoe work the secondary spans should be very short; the writer knew of no installation on which long secondaries had actually been tried out, but it would seem that the manifest economy, if the number of hangers could be materially reduced without impairing the efficiency, warranted careful investigation. The author's hope that further investigations would be made in regard to roller types of collar would be shared by all who had investigated the subject, and it was by no means impossible that a modification of the present form of trolley wheel might be of much value. The writer had for some time had in mind a shoe design in which the main pantagraph movement ranging through several feet should be effected by some positive mechanical device, probably a pneumatic cylinder, the air supply to be controlled by a sensitive contactor mounted on the main pantagraph. This contactor, having little inertia and therefore able to follow the wire almost instantly, would take care of variations within its range of about 1 ft. each side of the middle point.

Mr. O. S. Lyford, jun., considered the ideal conductor for the distribution of electric power for heavy railway operation was one that was either absolutely flexible or absolutely rigid, and parallel to the running rails. For low voltage work, which in heavy service involved the collection of large currents, the tendency was towards the rigid conductor, as characterised by the third rail. For high voltage work and consequent low current the tendency was towards absolute flexibility of structure, and catenary trolley construction had been the best development thus far. Improvements in third rail construction had been in the direction of greater rigidity and improvements in catenary construction towards greater flexibility. For intermediate voltages, it remained to be seen what construction would prevail and neither of these two, as now developed, was entirely suitable. There was still room for the development of a light form of pole to take the place of wood. One of the principal criticisms which maintenance-of-way officials made to electrification with the overhead trolley system was the danger to persons and property in the case of a derailment or collision which might result in overthrowing the overhead structure. It had been found that with wooden poles supporting a strong catenary structure, a derailment would result in cutting away the pole without bringing down the conductors. Heavy bridge work or heavy steel pole structures would not act as satisfactorily in such accidents. Referring to the various forms of catenary hanger illustrated, one point which should be looked out for was that the hangers should not damage the galvanising of the messenger cable. This cable was an expensive item of the catenary structure and one hard to replace without delay to the traffic. A form of hanger which had a flat loop over the messenger wire was, therefore, safer than a sister hook construction or any other form in which the cable might be more or less cramped. As Mr. Thurston had pointed out, the design of the loop over the messenger should be such that the hanger could be moved along the messenger easily. The author mentioned an excellent point about the disc type of insulator—that there was mechanical linkage of the guy cables on the opposite sides of it, which prevented their falling apart if the porcelain broke. This feature should be incorporated in all strain insulator construction. It could not, however, be incorporated in such wood strain insulators as were now employed, and this was one of the principal objections to the use of wood, as either burning or breaking of the wood would throw the overhead structure out of alignment and possibly cause it to drop.

Mr. W. H. Kempton raised a point in regard to the length of the brackets for a spacing of 8 ft. between the centre of the track and the centre of the pole. He found it was necessary to use a longer bracket on curves than on tangent, when the poles were placed on the outside of the curve. This was due to the rake of the pole in one direction, and the elevation of the track in the other. With these conditions it was necessary to use extra long brackets on curves, or longer ones everywhere. The author spoke of lining up trolley wires on the curves when pantagraph trolleys were used. The speaker thought it was unwise to allow as much deviation from the centre line on curves as was the practice at the beginning. There were four considerations to be borne in mind in this connection. One was the rake of the pole, (2) the elevation of the outer rail, (3) the speed, (4) the play of the bolsters on the car. At standstill or at slow speed on curves the pantagraph trolley tended to swing toward the inside of the curve; but when running round the curve at 40 miles an hour the momentum of the car threw it over on the bolsters towards the outside of the curve so that there was a difference of from 10 in. to 12 in. in the position of the trolley with respect to the wire. In one case, the line had been constructed very carefully, but in spite of that the pantagraph trolley would swing out free from the trolley wire and pull down some of the line or pull the trolley from the wire. It looked impossible from measurements on the line until it was discovered that the construction of the car allowed it to swing over on the bolsters when going around the curve at high speed, sufficient to throw the pantagraph clear of the trolley wire. The remedy in that case was to re-line-up the trolley wire and add more poles or pull-offs where necessary to reduce the offset of the trolley wire, and then fix up the car to avoid such excessive swaying. This was one of the personal experiences the speaker had had emphasising the care that must be exercised in the erecting of a trolley line on which pantagraph trolleys were to be used.

Mr. W. N. Smith, in reply, thought that Mr. Coombs had answered Mr. Thomas's question in respect to the secondary arm or tip which had sometimes been employed at the top of the main pantagraph. This device had been used on the Simplon tunnel locomotives with sliding shoe on the tip. The Simplon locomotives travelled with a maximum speed of 45 miles per hour and the contact shoes were of the sliding type.

Digitized by Google

Even with the lessened inertia of this device, the shoes only lasted about 1,700 miles. The fact that the old pole and wheel trolley operated so well with trolley wires having considerable sag, illustrated the importance of recognising wave action, which was so much in evidence with the wheel type trolley, and this confirmed his belief that the natural and desirable wave action in the trolley wire would be very much helped by the roller pantagraph, and with less wear and tear than with the sliding pantagraph. This point of view was based upon the probability that the heavy work of the future would be at high tensions—*i.e.*, at 11,000 volts or higher—and that the trolley pole and the narrow grooved wheel accompanying it would not be regarded as thoroughly reliable for high-speed operation under steam railroad conditions, so that it would be necessary to have a transverse rolling or sliding contact which would not leave the wire under any circumstances. With respect to the possible twisting in the compound catenary construction, where the wires were strung to a fairly even tension, and the hangers of the proper length, and all parts securely and tightly drawn up, there would not be any tendency to roll when the line was properly adjusted. Mr. Harte had emphasised the interesting fact that successful operation depended upon uniformity of resistance at the contact surface—*i.e.*, hard spots should be kept out of a yielding line, or soft spots out of a hard line—or, in other words, the line should be either uniformly hard or uniformly yielding. The successful operation of the Denver & Interurban catenary line had been due to the fact that it was uniformly hard and smooth. The experimental lines constructed with flexible hangers mentioned by Mr. Hixson and Mr. Harte would doubtless have considerable effect in determining the development of catenary details, but it now appeared that both the Schenectady and Connecticut lines were operating with wheel trolleys and not with sliding bows. It seemed that the contact-making conditions which must ultimately be fulfilled by equipment for heavy traction were not being met in these installations, and to that extent they would be somewhat inconclusive. If they should be tried out with pantagraph trolleys of the sliding or roller type, then there would be something definite upon which to base conclusions for the heavy and high speed work of the future. The question of clearance was, of course, one that pertained to conditions on each particular job; 8 ft. was mentioned as a minimum. He believed, however, that 8½ ft. was better, as used on the Denver & Interurban line. The roller type of trolley contact had been in use in Europe for some years; the Valtellina installation in Italy being perhaps the best known instance of its application there. He referred to its use on the Pacific coast as the first and only application of its use in America. Since writing the Paper he had ascertained that on the Valtellina line, where the overhead construction was not very tight (and not of the catenary type) the rollers had an average life of 15,500 miles and frequently carried more than 200 amperes per roller, and that in the opinion of Mr. Von Kando, of the Italian Westinghouse Company, the excellent life of the contact roller was due partly to the difference between rolling and sliding friction and partly to the fact that each element of the roller was heated by the passing current only at the instant of contact, and did not remain in contact long enough to get melted; while with the sliding contact the wear was excessive when the current was more than 50 amperes. It seemed to be agreed that the vertical flexible working conductor was very desirable, and the best reports of smooth operation with it emanated from installations where the rolling and not the sliding contact was used. It was his belief that trolley pole and wheel were not suitable for heavy railroad operation at high tensions and speeds, and that the horizontal transverse form of contact device was indispensable under such conditions, and he suggested that the next step forward should be in the development of the roller type of contact against the yielding or floating trolley wire, in which the elements of wire tension, contact pressure and pantagraph inertia would be compromised to produce the desired effect.

RESULTS OBTAINED BY THE USE OF CAR METERS ON TRAMWAYS.*

BY G. BOUTON.

From the answers to the *questionnaire* it appears that 37 undertakings have definitely adopted the method of controlling their motormen by means of meters. Twelve others are carrying on tests towards this end, while three, on the contrary, have definitely renounced the use of these instruments. It is interesting to note that in 1906 only 10 undertakings, and in 1908 26 undertakings, were using this apparatus, and thus it is evident a distinct step forward has been made.

The question which has to be solved to-day is not so much whether it is advantageous or not to control the work of the motormen by means of meters, but to choose between the different methods of applying this principle, between the apparatus and the method of using the results which are obtained. The two points of view from which the question can be considered, although very different in appearance, are in reality quite closely connected. With Mr. Wattman, the present reporter is of opinion that the solution of the problem differs from undertaking to undertaking, and that before making a choice each undertaking must weigh all the elements of success. These elements are fairly numerous. Perhaps the undertaking is one of those exceptional cases, where control by meters is of little use. It may, perhaps, happen that the undertaking is of little importance and that the motormen can be supervised easily and efficiently. If the price at which the energy is bought is extremely low, the consumption of light cars on level lines will be low, too. If, on the other hand, the system is composed of very hilly routes with frequent stops, &c., the consumption will be high.

If it is not considered that the undertaking is one of these exceptional cases, a choice must be made of one instrument or another, and, to begin with, all types whose regular operation does not seem to him to be assured should be placed on one side, for irregularity in the value of the readings obtained has one inevitable consequence, a loss of confidence both on the part of those who are controlled and of those who control them. There are at the present time no longer two but three types of car meters, each of which has its advantages and disadvantages; but these advantages and disadvantages are of different kinds, so that each system may best be accommodated with one particular type of meter.

After briefly describing the three types of meter in use and the disadvantages of each, the reporter goes on to point out that clock meters, although very simple, do not measure what one is trying to obtain, *i.e.*, the energy consumption of the car. Partisans of clock meters recognise in principle that this reproach is well founded, but they consider that in practice the indications which are obtained are just as good as those obtained from wattmeters in allowing an efficient control over the motormen. They further state that the question is more complex than simply determining the energy consumption; that what the manager requires to know is the greater or less skill of each motorman in expending only the minimum of energy possible in producing a certain amount of useful work. This work produced, which appears under the very simple form of a certain service effected, is in reality so complex that it is not possible rigorously to measure it. Allowing that its intrinsic value depends on a certain number of factors, some of which are of an essentially variable nature, such as the efficiency of the gearing, the atmospheric conditions, the number of passengers, the traffic on the routes, and the knowledge of the motorman, they consider that whatever type of meter is employed there must exist the same and rigorous proportion between each of the readings and the skill of each of the motormen whose work is judged by these readings.

The reporter is not impressed with this argument, considering the happy results that have been obtained on a large number of systems, but considers that the nature of the indications furnished by the clock meters constitute an inherent vice; while he thinks this type of meter contains a grave fault which in a number of cases should prevent its use. In 1906 Mr. Wattman suggested that comparative tests should be carried out between the two types of meter, and a question relating to this subject was placed in the present *questionnaire*; but of the 38 undertakings which have answered nine only say that they have made comparative tests between clock meters and watt or ampere-hour meters placed in series. Of these nine, four (Berlin, Nuremburg-Fürth, Wiesbaden and Zurich) say that they have obtained concordant results. One (Vienna) has noticed that on level runs there is generally agreement, but that this agreement does not continue on sloping lines. Four (Bordeaux, Marseilles, Munich and East Paris) have noticed a very considerable difference between the results given by clock meters and those given by watt meters or ampere-hour meters. In the presence of these contradictory declarations it would not be without interest to have a detailed account of the operations made by each undertaking in order to compare them. Only one undertaking (Bordeaux) has backed up its statement by figures, which show a complete absence of proportion between the indications furnished by the two classes of meter; in fact, the results obtained on three days for the same service with different motormen are as follows:—

Car No.	Time meter readings.	Consumption per car-mile. Kw.-hr.
104	6·53	1·10
	4·1	1·17
	6·19	1·20
128	5·27	1·12
	5·20	0·91
	5·50	1·01
82	5·35	1·12
	5·32	1·28
	5·20	1·15

The tests which the reporter personally made do not give any better results. During 1906 and 1907 two cars were fitted up with a

* Abstract of a report by Mr. Bouton, general manager of the East Paris Tramway Co., on the replies received by the Union Internationale de Tramways et de Chemins de Fer d'Intérêt Local, in response to the *questionnaire* sent out to the members, presented at the bi-ennial meeting at Brussels (1910).

Digitized by Google

clock meter, a wattmeter and an ampere-hour meter. Several tests were taken, but the results all showed very great discord between the readings given by the clock meters and those furnished by the other meters. In 1909, when the installation of ampere-hour meters had just been finished on all the cars, and the periodic classification of the motormen was being organised, it was desired again to discover whether it was really possible to obtain with clock meters the end desired. For this reason two clock meters were placed on two of the cars on the same line, and at the end of several days the motormen who had worked the cars were classified. They were 36 in number, and were divided into two lists, one arranged in the order of the results given by the clock meters and the other in the order given by the ampere-hour meters. The results of these tests are given in the accompanying table :—

Motormen.	Time per car-mile.	Consumption per car-mile.	Classification according to clock meter.	Classification according to ampere-hour meter.
A	2·16	1·637	1	18
B	2·86	1·595	3	11
C	2·90	1·427	4	1
D	3·04	1·648	6	19
E	3·09	1·522	8	2
F	3·23	1·851	10	35
G	3·33	1·722	14	29
H	3·33	1·528	15	4
I	3·58	1·731	21	31
J	3·68	1·610	24	12
K	3·71	1·557	25	6
L	4·11	1·528	33	3

A third list of motormen was also prepared according to the mean energy consumption per minute that the car was under current. This mean consumption varied between as little as 300 watt hours and as much as 600 watt hours; while, further, nine of the motormen who were classed amongst the 10 first, according to the clock-meter readings, were found amongst the 10 motormen whose consumption per minute under current was the highest, which tends to show that they obtained their classification, not by a real economy of energy, but by an abusive employment of parallel working. The results of these tests further indicate that with the clock meter the skill of the motorman is measured by means of a unit (*i.e.*, the time the car is under current) whose value, compared with the quantity of energy consumed, is susceptible of very great variation according to the way the car is operated. In consequence, the readings of the clock meter are not sufficient by themselves to determine the skill of the motorman. These indications can only be of real use when a very close control causes the motorman to work in a uniform manner according to the rules which have been laid down. This is only realised with difficulty, especially on lines in traffic, or else under the condition which is very seldom fulfilled (if the answers to the 14th question of the *questionnaire* are to be believed) of possessing a *personnel* which is sufficiently conscientious to follow the instructions, that are given without any inspector being necessary.

Certain supporters of clock meters argue that motormen who depart from these instructions can be recognised by the fact that the time which is measured on their meters is lower than that laid down for the standard journey. This might be true if the motorman were to work without discrimination, but it is easy for him to falsify the results which concern him, as shown by the case of motormen F and G in the table above. It is admitted by most of the members that clock meters do not permit a classification of motormen or the application of a system of prizes for economy. Clock meters have, on the other hand, indisputable advantages which up to the present time have made them more used than wattmeters on the majority of lines. They are both simple and robust in construction, and they scarcely ever get out of order; their first cost is low, while their upkeep is insignificant. Certain undertakings remark that the indications such instruments give are more easily understood by their *personnel* than those furnished by current meters, the notion being that time is more easily intelligible to the motormen than energy consumption. Further, the readings can be made easily at the end of each journey. On the contrary, it is stated that the use of clock meters causes the motormen to exaggerate the speed in starting. This appears to be confirmed by the answers on the subject which have been made to questions 3 and 14 of the *questionnaire*. Some members have remarked that starting, which is obtained by cutting the resistances out very quickly, has the effect of decreasing the resistance losses, and thus increasing the useful effect during the period of acceleration. In consequence, the wattmeter, which registers the energy absorbed by the resistances, should incite (as does the clock meter) the motormen to start rapidly. This fact is in itself true, but it must be added that if from the point of view of starting the two types of meter exercise their influence in the same sense, they exercise them in a different degree, for if the wattmeter gives the motormen exactly the benefit realised by starting quickly, that benefit is of the order of 5 per cent., while the clock meter registers favourably to the motorman a fictitious benefit which is much greater than the real benefit. Starting quickly leads, in fact, as we have shown above, to the motormen using the most efficient means of changing the value of the unit or the quantity of the ener y consumed; in fact, the error in the case of the clock meter is of the order of 10 or 12 per cent., as compared with 5 per cent. The ampere-hour meter differs from the wattmeter in the fact that the motorman when starting quickly produces a rush of current, so that the line voltage is diminished, and this is not registered on the ampere-hour meter. This, therefore, makes but a small advance which tends to counterbalance the economy realised by the starting quickly.

Several undertakings where clock meters are used stated at the Munich Congress, and repeat the statement now, that the effect of starting too rapidly operates unfavourably on the upkeep of their motors, particularly on the armatures, the commutators and the brushes. Certain others have, however, noted no aggravation of this kind. Two of them, in fact—viz., Barmen and Frankfort—see nothing but an advantage in the fact that their motormen are incited to start too rapidly, for their motors do not appear to be worn out in any way. It is certain that the influence which rapid starting must have on the motors should vary from one system to another in accordance with the power of the motors compared with the work they have to do. There is no doubt that the system which does not possess very generously designed motors should make every effort to avoid a rapid starting. As we have seen above, the meters afford to various systems which use them advantages which differ according to type and design. It may, however, be remarked that they all have one common advantage in the fact that the motormen know they are being submitted to continual control.

The types of meters at present employed are three in number—viz., the wattmeter, the ampere-hour meter and the clock meter. The first of these is most complete, as it makes a true comparison, in which each motorman in each car possesses a certain rank in accordance with the energy consumption. It is more complex, however, and more costly than the second, which consists simply of the classification on the "dossier" of each motorman, and on the way bills, of the readings given by the meters, and the average time during which a car is under current for the service it has undertaken. The first allows a proper classification of the motormen to be obtained, while the second simply points out those who are working in a reprehensible manner.

We have just seen that in determining the method to be adopted the question of cost comes in. The first cost and upkeep varies very considerably with the type of meter employed. As, however, there exists a close relation between the type of meter and the method of using it, we have brought together these considerations of expense in order to examine them.

It appears from the answers to the *questionnaire* that the first cost and cost of installation varies for wattmeters between £3. 14s. and £9, the average price being £5. 8s., which, supposing that the life of one of these instruments is 187,500 car-miles, works out at 0·007d. per car-mile. For ampere-hour meters the price is between £4. 5s. and £5. 12s., the average being £4. 16s., or 0·006d. per car-mile. For clock meters the price is between £1. 14s. and £5. 4s., the average being £2, or 0·003d. per car-mile. The running expenses vary per car-mile between 0·002d. and 0·005d. for wattmeters, the average being 0·003d.; for ampere-hour meters between 0·002d. and 0·005d., the average being 0·003d.; for clock meters between 0d. and 0·001d., the average being 0·0005d. The administrative expenses vary per car-mile between 0·004d. and 0·05d. for wattmeters and ampere-hour meters, the average being 0·01d., and between 0·0002d. and 0·0009d. for clock meters, the average being 0·0004d. The total expenses per car-mile are, therefore, for wattmeters 0·02d., for ampere-hour meters 0·016d., and for clock meters 0·004d. In order further to determine the advantages which the low cost of the clock meter should bring to the system, it is necessary to take into account the value of the energy which each meter measures, a value which varies according as the price of the energy is high or low, as the weight of the cars is small or great, as the system is flat or hilly, between 0·4d. and 1·33d. per car-mile. Bringing these figures into the calculation, it appears that in the lower limit the advantage of the clock meter, from the point of view of expense and compared with watt and ampere-hour meters, is from 2·3 to 2·5 per cent. of the value of the energy it controls, while in the upper limit this advantage is only from 0·75 to 0·69 of 1 per cent. The advantage of the clock meter in requiring lower costs to operate it should only exercise on the choice of the meter an influence as variable as the conditions under which each system works.

Digitized by Google

The last question which has to be examined is that regarding the methods employed by those systems using car meters to obtain from their motormen a judicious employment of the energy which is placed at their disposal. An analysis of the answers to the *questionnaire* shows that 17 members stimulate the zeal of their motormen by means of prizes or gratuities, combined with repressive measures. On the other hand, 18 members work upon their staff simply by repressive measures, reprimands and instruction courses, or, by means of these measures combined with rewards for the best of the men, or by publishing the results obtained periodically. Some of these 18 members express themselves strongly against any system of prizes.

It is undeniable that a system which consists in the distribution of money prizes among the *personnel* carries with it difficulties which it is not easy to overcome. Its application requires great circumspection on the part of the management. The answers to the *questionnaire* show that there exists at the present time certain undertakings which at first were partisans of a prize system, but have now abandoned it, while others have adopted it. The reason for this is, as before, that the choice varies with the peculiarities of the methods of working.

At the Milan Congress Mr. Wattmann said: "Mr. Koehler, of Berlin, thinks that on important systems the allocation of prizes to motormen cannot be avoided, but immediately afterwards he shows the dangers which such an arrangement causes, especially on important systems. For my part I share in the fears of Mr. Koehler, and I have expressed myself very circumspectly on this subject in my report. The allocation of prizes has already given rise to difficulties in certain undertakings, the evil can only advance with the progress of the socialist movements. On wide-spread systems especially the principle of equality is placed in the forefront. No one, it is said, should receive preferential treatment. The movement which is being made with regard to the equality of salaries would also be applied to prizes."

It seems, in fact, to be very difficult, if not impossible, to impose a system of prizes on a *personnel* which does not want it. Recourse in such a case must, therefore, be had to other means. Without knowing exactly the number of undertakings which meet with such hostility, and which have, therefore, replied to the *questionnaire* unfavourably, we are right in saying that the 17 undertakings which give money prizes represent the great majority of those which are allowed a freedom of choice by their *personnel*. We may incidentally remark that although this spirit of opposition is shown in Germany, especially among the *personnel* on the railways and in certain industrial centres, it is by no means general up to the present. The socialistic spirit has not advanced in the same way in all countries. In Belgium, as well as in France, the principle of individual prizes continues to be acceptable to the industrial world, and especially to the railway and tramway *personnel*. There are numerous undertakings which either are already using meters or are proposing to do so in the future, and who find the bestowal of prizes is favourably considered by their *personnel*.

The answers to the *questionnaire* show the primordial interest which is taken by certain undertakings in the bestowal of prizes. For instance, at Hamburg a system of prizes based on the economy in energy consumption realised year by year compared with that consumed in 1902 was instituted. At a certain period the value of these prizes decreased, owing to the fact that the traffic had considerably increased and that the results obtained in 1902 became, therefore, inapplicable. Far from doing away with the prize system, its superiority was so far recognised that a new basis of calculation, more favourable to the *personnel* was adopted.

It should not, however, be forgotten that the principle of prize giving is a delicate one. When its adoption has been decided upon, a judicious choice should be made between the arrangements used, while the basis on which the prizes are to be given should be determined with prudence and care. Whatever methods are adopted, they will require the periodical calssification of the motormen, and in consequence, there must be a choice between watt meters and ampere-hour meters, to the exclusion of the clock meters, so that the decision is closely connected with the choice of the type of meter, and is governed by the same considerations as is the latter.

It should, however, be noted that the employment of clock meters is only compatible with a peculiar system of prizes, which consists in giving a certain gratuity monthly to all motormen who are above a certain standard. This amount is fixed by the mean consumption per car-mile during the month. This method of operation, though there is little to commend it, is adopted by several undertakings.

It appears that Amsterdam combines the results obtained by means of clock meters with a verification of the passing times at certain points on each route. This is effected by control clocks, and is said to give satisfactory results. At Brussels "automatic" starting resistances are used. These possess the peculiarity that their resistance decreases when the current passes through them, so that an acceleration of the car is progressively produced without the jumps that occur when passing over controller notches. From Hanover there is a suggestion that apparatus for indicating when too rapid starting takes place should be used

An analytical study of the various results set out in the above reports leads to the following conclusions:—

1. In a general way it is recommended that the work of motormen as regards energy consumption should be controlled by means of meters. This control is only truly efficient when each car is fitted with a meter.

2. The application of this control can be effected in two ways: In the first, with a view to ensuring that the individual motorman consumes the lowest amount of energy compatible with the necessities of the service, an influence is exerted on the *personnel* by distributing among the most skilful pecuniary prizes whose value is proportionate to the results obtained, while at the same time disciplinary measures are taken against those whose work leaves something to be desired. This method requires the periodical classification of the *personnel* by determining, as exactly as possible, the relation between the energy consumed by each motorman to the standard energy consumption for the work done. This method also predicates, as a logical conclusion, the employment of either a watt or ampere-hour meter.

In the second way an attempt is made to get the different motormen to do their work in as uniform manner as possible. They are no longer classed according to the energy they consume, but by the way they differ from a standard line of operation. In this case a clock meter may be employed, the results which it gives being sufficient, always allowing that its work is supplemented by personal supervision, which must increase as the *personnel* becomes less conscientious.

3. If a system is operated by a *personnel* who are favourable to the idea of rewards, while the system itself is of such a nature that supervision of the motormen is difficult, while the amount of traffic leads to frequent stoppages, the gradient profile is irregular, the cars are heavy, the motors closely designed, the price of energy is high, &c., all conditions tending to increase the influence of the motormen on the operating expenses, the solution given first above is to be recommended.

If the conditions under which the system operates are quite the reverse of these, the second solution is preferable.

In an intermediate case it must be decided which of the conditions set out above have the most influence, in order to determine the final result and to be able to make a choice.

If the system is of little importance, making the supervision of the motormen easy and efficient, the price of energy low, the energy consumption of little importance owing to the infrequent stops, the cars light, the lines level, &c., it might even be preferable not to control motormen by means of meters at all.

4. There are at the present time on the market meters capable of satisfying both the first and second solutions. With regard to the first, watt meters, though giving satisfaction on certain important systems, have been the object of disparaging remarks. It would, therefore, rather savour of temerity to recommend their employment, especially as their manufacture has not been subject to any recent improvements. But ampere-hour meters have now been proved, and their employment may therefore be recommended.

When the second solution is adopted the use of the clock meter is particularly recommended.

EXPERIMENTAL APPARATUS FOR WIRELESS TELEPHONY.

The interest concentrated upon wireless telegraphy owing to its application to the transmission of news has been materially increased by the possibility of wireless telephony. In order to demonstrate this branch and to facilitate the study of the subject, the apparatus described below has been constructed by E. F. Huth, of Berlin. By its aid it is possible, with a mast of 5 ft., to transmit music as well as the human voice over a distance of about 50 metres. By the use of a longer and higher aerial line this distance can be considerably increased.

The apparatus is made of two different types. The simple form consists of two stations, one of which can transmit, the other, receive; between these stations, therefore, speech in one direction only is possible. The more complete equipment allows of speech in both directions. It consists, therefore, of two stations, each of which is arranged for transmitting as well as for receiving.

Digitized by Google

Figs. 1 and 2 show a station for speech in one direction only. The transmitting set (Fig. 1) is mounted on a case of polished ash about 37 cm. by 50 cm. and 10 cm. high. It consists of a generator for continuous electric oscillations, transmitter coil and microphone. The case, which is fixed on an iron frame with castors for wheeling it from place to place, contains the Leyden jars and the choking coils. The receiving set (Fig. 2) is mounted on a small board, and consists of a receiving coil, detector and double head-piece telephone receiver.

The appearance of the set for working in both directions with antenna opened is shown in Fig. 3. The transmitter and receiver

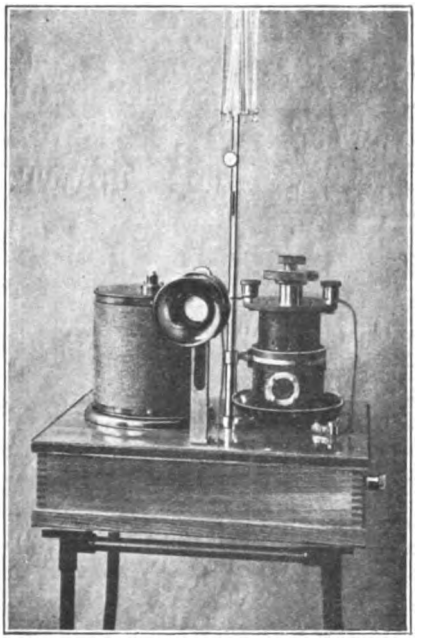

FIG. 1.—WIRELESS TELEPHONE STATION FOR SPEECH IN ONE DIRECTION ONLY.

are both mounted on a small case (Fig. 4). Inside the case are fixed the Leyden jars, choking coils and the automatic main switch. The lid of the case can be opened, thus making it possible to get at every part and to trace the connections (Fig. 5).

The case carrying the apparatus is mounted in the same way as in the set for working in one direction, viz., on an iron frame, about 90 cm. high with castors. It is, therefore, very easy to wheel the set about together with the antenna wherever it may be wanted.

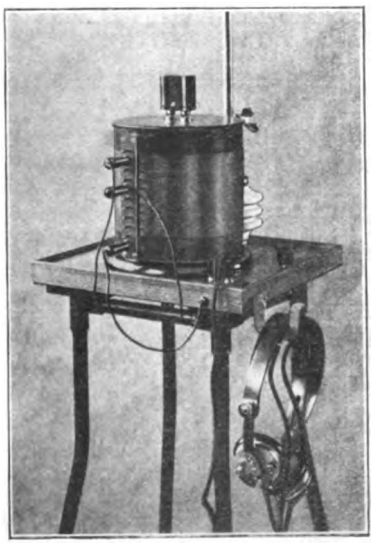

FIG. 2.—RECEIVING STATION.

In both of these sets the cases are attached to the frames by screws and can easily be removed. The main parts of the set, viz., generator, microphone, antenna, &c., can also be taken off and used separately; different experiments can, therefore, be made with a single apparatus. It is simple to demonstrate the principles of wireless news transmission, as also Tesla's and any other experiments depending upon the use of electrical oscillations of high frequency.

If required, the apparatus can be arranged for wireless telegraphy and in connection with a Morse telegraph instrument written messages can be obtained.

Connections.—The diagram in Fig. 7 shows the connections used in the sets for working in one direction only or in both directions. The connections in the set for working in both directions are shown in Fig. 6. By closing the plug connection continuous current at 220 volts flows through a choking coil to the arc generator, in parallel to which is an oscillation circuit consisting of self-induction (transmitter coil) and a capacity (Leyden jars). From the transmitter coil, which is connected at the upper part with the antenna, a branch connection is made through a Leyden jar and a microphone to earth; the coupling between the generator circuit and the antenna is therefore direct. By reversing a switch (automatic), which in Fig. 7 is shown turned to "transmitting," the receiving circuit is put in. It consists of the receiving coil, the thermo-detector (cell) and a double-head telephone. All three instruments are connected in series. Part of the receiving coil is connected to the antenna; the coupling in this case is also direct.

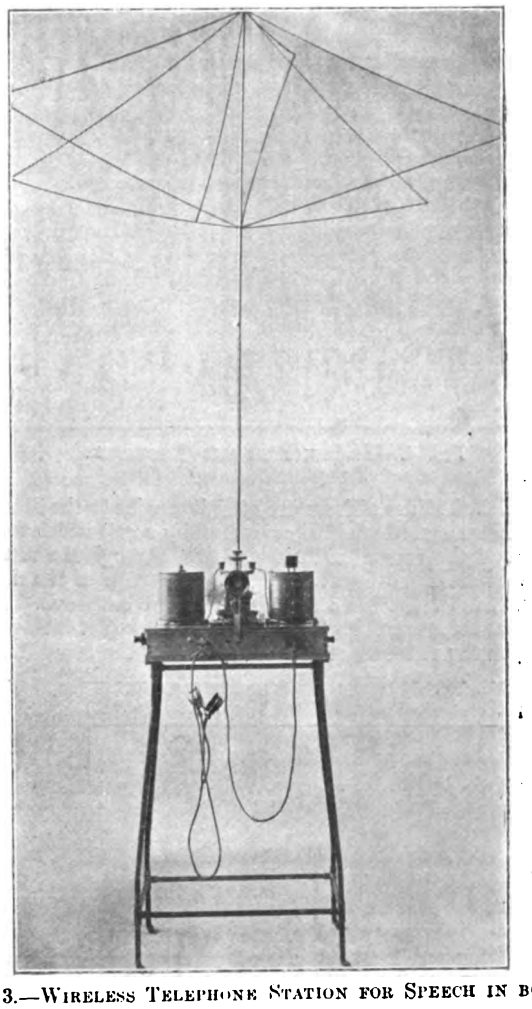

FIG. 3.—WIRELESS TELEPHONE STATION FOR SPEECH IN BOTH DIRECTIONS.

APPARATUS.

The instruments are the same both for working in one or in both directions; the latter only, therefore, will be described.

Transmitter.—The transmitter consists of the following parts: The choking coils are wound with enamelled wire. They are fixed inside the case, on which the separate instruments are mounted (Fig. 5). The generator (British patent 15,891/09) is constructed on a new method for producing continuous electric oscillations. The generator, as shown in Fig. 8, is worked by an arc between two carbon electrodes of a special form.

In Figs. 9 and 10 different forms of electrodes are depicted. In both cases the electrodes consist of tubes the ends of which are conical. In Fig. 9 the upper electrode projects into the lower. The arc is started at the place where the electrodes are nearest to each other, and is driven outwards by the heated air. It is then lengthened, owing to the conical form of the electrodes, and finally broken.

The advantage of this system is, that undamped electric oscillations of great constancy can be obtained without using special blow-

Digitized by Google

out arrangements or magnetic blow-outs. By using methylated spirit or any other quickly evaporating liquid, which surrounds the lower electrode and increases the blowing out of the arc by its evaporation, the intensity of oscillations can be increased.

In order to secure an even consumption of the electrodes, which is very important for a constant generation of oscillations, the arc rotates electromagnetically. For this purpose the arc is in a magnetic

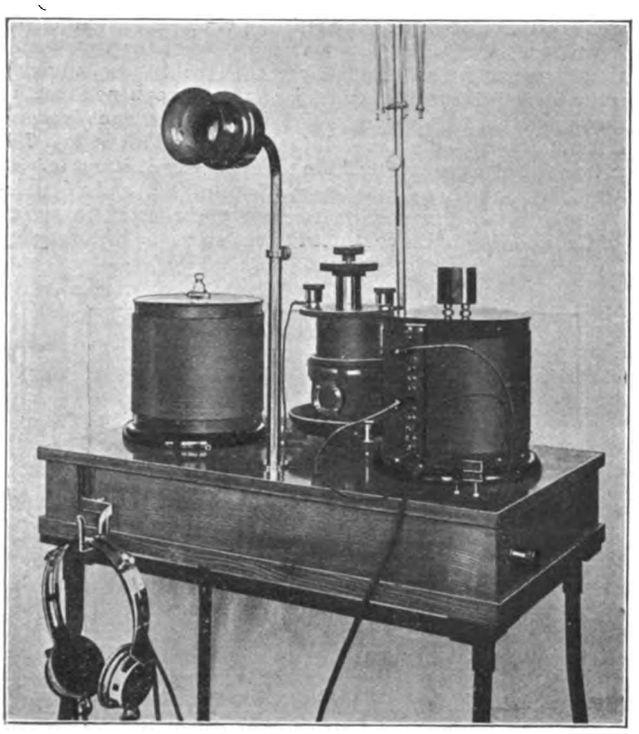

FIG. 4.—TRANSMITTER AND RECEIVER.

field, of which the lines of force are at right angles to the direction of the arc. The magnetic field is generated by a coil which forms the upper part of the generator. Besides this, through the rotation of the arc, the breaking influence caused by the shape of the electrodes is increased, as the arc has a tendency to curve outwards.

The generator is started automatically. The coil, which generates the field for the rotation of the arc serves, at the same time, as a striking coil. It is connected in series with the arc electrodes. When

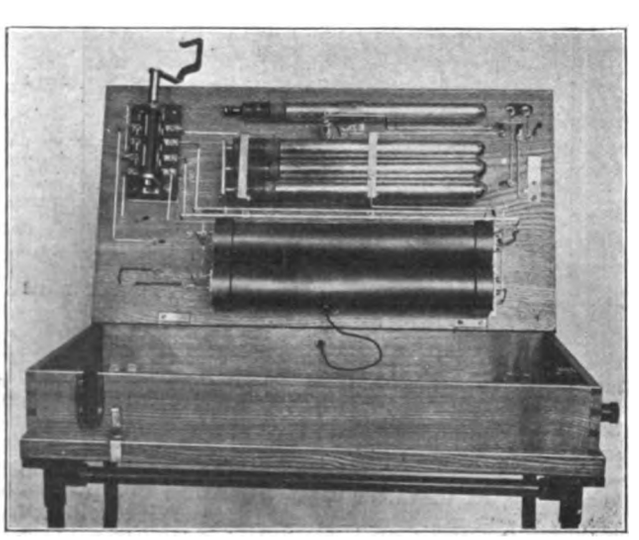

FIG. 5.—INTERIOR OF CASE.

no current is passing through the generator the electrodes are in contact; when current is applied, the upper electrode, which is composed mostly of magnetic material, is drawn into the coil and the arc is produced. By turning the knob at the top of the electrode any length of arc required can be obtained.

By the striking arrangement the operation of the generator is greatly facilitated. If the arc be extinguished, which may happen when too much energy is taken off, or when the power of the primary current is too small, it is indicated by a "knocking" of the ignition electrode. The electrode drops down, the circuit is again completed, the electrode is drawn into the coil again, and so on. The generator thus automatically indicates a mistake in its working.

A knob which is fixed to the upper part of the electrode makes it possible to start the generator by hand. The upper part, consisting of striking coil and electrode, is fixed to the lower part by a bayonet joint. By turning the upper part through 120 deg. it can be lifted from the lower part in the simplest way in order to adjust the inner parts of the generator, to put in new electrodes and to fill up with methylated spirit. The lower part consists of a cast-iron basin, which carries the other electrode in its centre. A mica window in

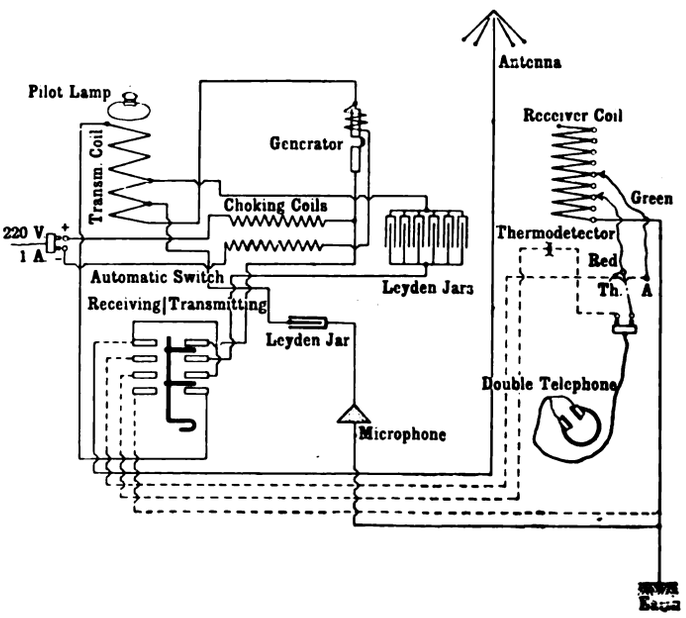

FIG. 6.—RUN OF LEADS.

the front makes it possible to control the arc with the generator closed. Opposite the window is a valve serving to regulate the pressure. The weight of the complete generator is about 3·5 kilos.

The self-induction exciting coil consists of stranded copper wire, the single wires of which are carefully insulated from each other. It is wound on a presspahn cylinder and afterwards soaked with a non-hygroscopic varnish. A few turns of copper wire which are in series with a glow lamp are coupled inductively with the transmitter coil. As soon as oscillations are generated, which also flow through the transmitter coil, the lamp begins to glow. This serves not only as a detector of the oscillations, but also as an indicator of their intensity.

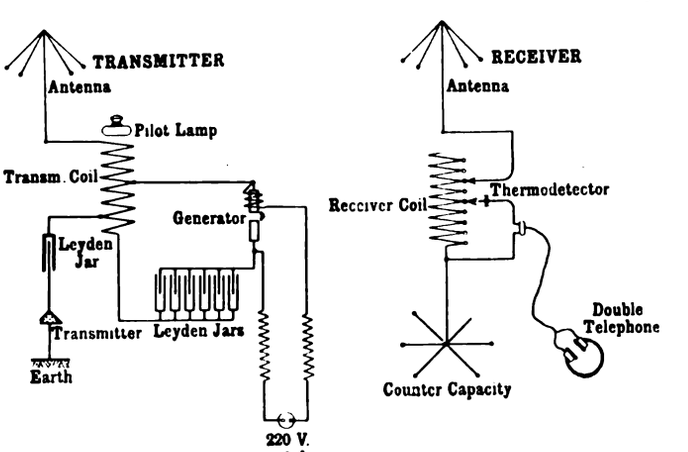

FIG. 7.—HOOK-UP.

The Leyden jars (Fig. 5) have a collective capacity of 3,000 cm., and are six in number. The microphone is of the strong current type. It can be moved vertically and easily be changed.

Receiver.—The receiving coil consists of wire strand which is finely subdivided and wound on a presspahn cylinder. At every 10 turns a connection is taken out and led to a plug, of which there are 13. By means of two plug sockets the necessary tunings can be effected. The leads to these sockets are placed side by side in ebonite inlet

Digitized by Google

tubes. The wire covered with green, connects the coil with the antenna, the red covered wire, with the thermo-detector and the double-head telephone.

The thermo-detector, which is mounted on the receiving coil, is constructed in the form of a two-polar plug. It is adjustable and can be interchanged. It is not sensitive to shaking and practically independent of changes in temperature. The telephones are of high resistance. The diaphragm and the connecting clip are adjustable.

Antenna.—The antenna consists of an umbrella-shaped nickel-plated frame, which can easily be closed and opened. When closed it is 133 cm. high, when opened it is 240 cm. high, with a diameter of

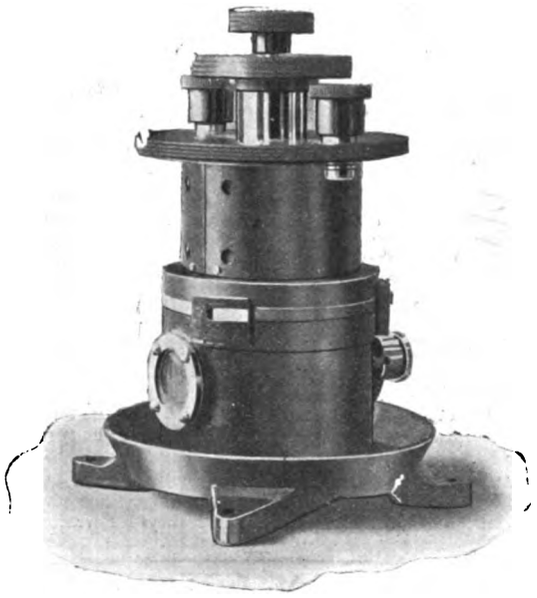

FIG. 8.—GENERATOR.

165 cm. The antenna is insulated from the iron frame of the station by a porcelain grooved insulator.

When speaking with the sets for working in both directions, the main switch, which at the same time carries the telephone, must be pulled down. This is effected by leaving the telephone on the holder, and later on, when the apparatus is adjusted, by pressing it down by hand. The earth terminal can simply be connected to a gas or water pipe. In order to start the generation of oscillations the plug is put in and the generator filled with methylated spirit up to the upper rim of the brass holder carrying the lower electrode. This done, the current is regulated at a pressure of 220 volts to about 1·0 ampere, and the arc started as small as possible, increasing it by degrees till the pilot lamp glows with a moderate light. The arc should then begin to rotate about twice a minute.

When oscillations are generated, and the microphone spoken loudly into, the

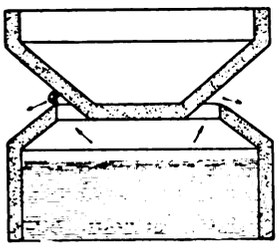

FIG. 9.

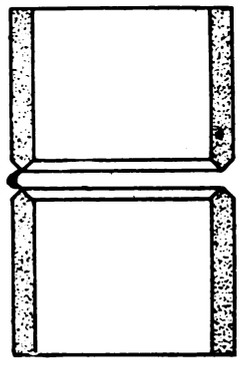

FIG. 10.

lamp will burn duller or brighter, according to the change of resistance caused by the microphone.

Wireless telephony, quite contrary to wireless telegraphy, came into practical use very slowly. It remained in the laboratory, and at present, four years after the invention of Poulsen, we note the first beginnings of commercial use. It appears that the importance of wireless telephony has been very much underestimated, all the trials in this quarter being considered as laboratory experiments.

The apparatus described above for demonstrating wireless telephony has been constructed to prove the contrary. It shows that neither complicated apparatus nor difficult instructions are necessary, and it is suited to convince anybody of the possibilities of wireless telephony for practical appliance.

The manufacturing company, Dr. E. F. Huth (Ltd.), of Berlin, has also constructed complete stations for wireless telephony for distances up to 50 miles. The company has a special type of a telephone station with a range of 5 miles, using masts 40 ft. in height. This station is made particularly for use with spark stations on board ship with a view to facilitate conversation between ship and ship in harbour or while under sail.

THE THOMAS YOUNG ORATION.

On Thursday evening of last week Prof. R. W. Wood, of Johns Hopkins University, gave, as the annual Thomas Young oration before the Optical Society, a very interesting account of some of his work in the domain of optics. He first described the making of what he terms "Echelette" gratings. As is well known the efficiency of a prism in spectroscopic work is in one respect greater than that of a grating, because all the light goes to one spectrum, whereas several spectra are produced from a beam of light falling on a grating. Nevertheless, it has been found that by suitably ruling the light from a grating may be concentrated mostly into a single spectrum, but so far it has been found impossible to determine what shape of groove in the ruling produces this effect, as the lines are so extremely close together. In order to investigate this question, Prof. Wood ruled gratings with very much larger lines and worked with heat waves instead of light waves. In order to obtain regular ruling it was necessary to get a very definite form of groove. As a material for gratings alloys were found to be useless, because they were not sufficiently homogeneous; pure metal was found to be necessary, and a film of gold deposited upon copper was finally used. There was some difficulty in getting optically flat copper, but the plates used for producing half-tones were found to be fairly satisfactory. Having deposited a film of gold upon such a plate the ruling was effected by means of a crystal of carborundum mounted in solder. The crystal was used in its natural state, and produced grooves whose sides made an angle with each other of 120 deg. In this way gratings were ruled with lines varying from 7,000 down to 1,000 or 2,000 per inch. It was found that no metal was actually removed in the process, the crystal merely making an impression, though sometimes some metal was broken away rendering the grating useless. The angle of the sides of the groove to the normal was varied by changing the setting of the prism. As such ruling did not necessarily give curves having the angle of the crystal, owing to the fact that any groove might be modified by the ruling of the next subsequent groove, it was necessary to measure the angles obtained. Owing to the breadth of the ruling this was possible by means of a spectrometer. It was necessary to obtain grooves without any plain metal between them, and this quality was checked by observing that the gratings did not give normal reflection from normal incidence. The finer gratings could be tested by means of light waves, and they showed a number of spectra each side of the normal, as is usually the case with a grating, but in addition to these spectra it was noticeable that, after a large interval, a strong band of reflected light occurred, on each side of which there were spectra of a high order, such as the 33rd to 35th. This was found to be due to the fact that the grooves were of such a size as to have a difference between their faces of 34 wave lengths in the reflected light, and consequently the grating in addition to acting as an ordinary grating acted like an Echelon grating. It was found that with suitable conditions heat waves were practically all concentrated into one spectrum.

In the concluding part of his discourse Prof. Wood gave an account of the "mercury telescope" which he has been using. In this telescope the reflector consists of an iron dish containing mercury set in rotation, the weight of the mercury being 50 lb. and the dish being 20 in. in diameter. When the dish is set in rotation the mercury assumes the shape of a paraboloid, the length of the focus depending on the speed of rotation. The difficulty is that if mercury is subjected to any vibration it becomes useless as a mirror. In order to avoid vibration the iron dish is drawn round by a spider through the medium of elastic threads, and the spider, which is motor driven, is entirely clear from the supports of the rotating dish. A plane reflector surmounts the telescope. As to the sensibility of the arrangement, Prof. Wood found that he was able to detect very small craters in the moon, such as are only just noticeable in photographs taken by the large telescope in the Lick Observatory. Consequently, there is some advantage in the system owing to its cheapness, though there is some difficulty in obtaining perfect definition.

In conclusion, Prof. Wood showed some exceedingly interesting landscape photographs taken by means of heat waves beyond the limits of vision. In these it was noticeable that the sky was practically black, whereas a great deal of the foliage appeared to be bathed in bright sunshine, or even covered with snow.

The Rates for Subscription to "THE ELECTRICIAN" are as under:—

	Year.	Half-Year.	Quarter.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Canada	28s. 3d.	14s. 6d.	7s. 6d.	
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	

New volumes of "THE ELECTRICIAN" *commence in April and October.*
(This charge includes all Supplements.)
Vols. I to LXIV. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Dec. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s; Europe, 2s; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription, 5s., post free.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three Separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.
VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free, abroad 13s.

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms, bound strong cloth. Price 7s. 6d. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d nett.

RADIO-ACTIVITY. AN ELEMENTARY TREATISE FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement was published (Gratis) with the number of "THE ELECTRICIAN" for September 23.

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various industrial purposes.

SPECIAL NOTICE.

The present number of "THE ELECTRICIAN" completes Vol. LXV. The Index to the Volume will be issued (Gratis) on October 21st.

READY SHORTLY.—Vol. LXV. of "THE ELECTRICIAN." Bound in Publisher's covers. Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.

Cases for binding Vol. LXV. are now ready, price 2s.: post free, 2s. 3d.

HYSTERESIS LOOPS AND HARMONIC ANALYSIS.

THE magnetic hysteresis loop, with its graceful symmetry, was bound sooner or later to fall a victim to the inquiring mathematician armed with FOURIER'S theorem. In fact, ever since Dr. J. BUCHANAN wrote to the "Philosophical Magazine" in March and November, 1901, it has been reduced to the ranks of "the harmonically analysed"; and now most teachers of electrical engineering, who possess oscillographs, exercise their students in finding the components of the no-load current in transformers, a process essentially equivalent to analysing the hysteresis loop. It has been reserved for Prof. S. P. THOMPSON, however, whose recent Physical Society Paper we reproduce in abstract on another page, to deal with this matter in the most comprehensive and illuminative manner. Of necessity his method of analysis is fundamentally that suggested and carried out by Dr. BUCHANAN; only, by employing an adaptation of RUNGE'S well-known method of harmonic analysis, he is enabled to obtain his components with greater facility. It is, however, in the very elegant way in which the components, once obtained, are combined and presented graphically in the form of a series of LISSAJOUS' figures, and in the deductions which he draws, that the chief value and novelty of his Paper consists.

One's only fear is that, with the simplification of methods of harmonic analysis, every analysable function

Digitized by Google

will be resolved into its sine and cosine components whether there is any real justification for it or not. Certainly to many it will appear one thing to analyse by a dynamical and, in a sense, natural process, say, a compound ray of light into its simple vibrations by means of a prism or grating, and quite another to analyse a hysteresis loop into harmonic components by a method purely trigonometrical and more or less artificial. In the one case each simple vibration has a traceable physical cause, the presence or absence of a particular vibration revealing something definite about the physical condition of the body emitting the light; whereas it is by no means always obvious what a given harmonic component of a hysteresis loop actually means, or to what it owes its existence.

To some, even, it may not be at all clear that much useful information is in reality gained as to the magnetic processes at work by stating that the power conveyed to the iron core of a transformer, with a fixed sinusoidal E.M.F. across its primary, is proportional to the co-phasal component of the fundamental harmonic in the magnetising current; any more than a knowledge of the character of an arc, burning under a fixed sinusoidal E.M.F., is gained by saying that the power absorbed by it is proportional to the co-phasal component of the fundamental harmonic in the current.

Such objectors will very probably point to the remarks of Dr. L. A. BAUER, contained in an address on the "Meaning and Method of Scientific Research," delivered before the Philosophical Society of Washington on December 5th, 1908 ("Nature," February 18th, 1909, p. 473), as voicing their scruples in this matter. Dr. BAUER, in his remarks—which have special reference to geo-physics but are equally applicable to other branches of physics—maintains, with some show of justice, that harmonic analysis is very often applied regardless of its suitability or necessity, and his question, "Does the resolution into Fourier terms of a phenomenon of the kind given really prove their existence in Nature?" sufficiently reveals an attitude which is doubtless shared by many. However, with proper reservations, and always bearing in mind that a thing is not necessarily physically existent simply because it is mathematically derivable, we may willingly admit that the process of harmonic analysis has its own fit and proper place in physical work, as has the corresponding process of resolving forces into their components, with which it may indeed be compared, and with which it ranks as of at least equal importance and utility. But it must be remembered that, like the resolution of forces, it is more often a means than an end, and care must invariably be taken not to put upon the results to which it leads any construction that they were never intended to bear, and, in particular, not to imagine that we have succeeded in arriving at the true nature of some special periodic effect merely by resolving it into its harmonic constituents.

Prof. THOMPSON is, of course, far too experienced not to avoid such pitfalls, and although the practical man who has to build and work transformers, and who is unversed in the arts of analytical geometry, may very probably regard his treatment as far-fetched and uninstructive, yet to many his methods will appeal as especially elegant and his conclusions as highly suggestive. The fact that his results are in their very nature empirical in no way detracts from their value; for in our present state of ignorance regarding the precise molecular laws upon which the phenomenon of hysteresis depends, the establishment of an empirical formula is all that anyone can hope to achieve.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Die Fernsprechtechnic der Gegenwart. By C. HERSEN and R. HARTZ. (Brunswick: F. Vieweg & Sohn.) Pp. 128. M.2·50.

The title of this work is somewhat too comprehensive for the ground covered, for the authors deal only with what is known as the "inside plant," namely, the exchange and subscribers' equipments. The authors do not make any attempt to deal with the subjects of transmission and traffic which form perhaps the two most important branches of telephone engineering of the present day. The authors explain in the preface that they have so limited themselves, but we think a clearer indication of the restricted scope of the work might have been made in the title.

The book forms, however, a valuable record of Continental practice and ideas in the design of exchange equipments and apparatus, and also of the various types of instruments used in subscribers' offices. In addition to the apparatus of Continental design a considerable amount of space has been devoted to descriptions of American types.

We are glad to note that the authors have attempted to treat the subject in the only way which is of the slightest use in a science which is developing so rapidly as that of telephony—namely, by dealing very clearly with the fundamental principles underlying the design of the various circuits and apparatus. The diagrams of connections especially are simplified to show the working of the circuits, so that the reader is not confused with details of connections and wiring necessary only to the wireman.

The illustrations are very numerous, and no use has been made of half-tone blocks, with the result that the figures are all refreshingly clear and distinct.

The authors commence with a detailed description of the essential parts comprising a subscriber's instrument and their connection, and pass on to consider the terminal and protective apparatus for the line. The details of the exchange apparatus are then fully dealt with, and connection diagrams are given for all the most important systems of central battery working. The attempts to reduce the extent of multiple required by such devices as group working, divided multiple and transfer working are then dealt with. Trunk line working and simultaneous telegraphy and telephony are explained. The treatment of extension working is not very full and leads one to believe that this has not reached a very high state of development on the Continent. Private branch exchange systems, however, receive due consideration, while miscellaneous auxiliary appliances and circuits such as for registering calls, service observation, &c., are also included. The last chapter deals with the lay-out of exchange buildings; this part of the subject might well have been given fuller treatment.

The work under review does not select any particular system for specially full treatment, but deals with many as if they were practically of equal importance. This leads one to the conclusion that telephony in Germany is in a condition rather similar to that existing in England some years ago, when several different systems were under trial, except that in Germany the various systems are more modern and individually better.

English practice is barely mentioned, and the book will, therefore, prove interesting and useful to English readers as a book of reference rather than as a text book. The impartial treatment which each system receives increases its value in this respect.

In addition, there are explanations of many details of design and manufacture of apparatus not to be found in English works, which deal with the subject more from an operating than from a manufacturing point of view.

Electric Power Conductors. By Wm. A. Del Mar. (London: Crosby, Lockwood & Son.) 9s. net.

In the present work the author gives a very comprehensive and concise account of the facts concerning the use, properties and sizes of electric power conductors. It is replete with reliable and useful data which will be welcomed by all engaged in the calculation of underground and overhead mains and cables. The author has been at considerable pains to give an enormous amount of information, based on his own large experience in transmission work in America and culled from the writings of the best-known authorities, to whom reference is always made, in a form directly applicable by the practical man. An excellent book has, however, been somewhat spoilt by the very apparent carelessness with which the proofs have been read, and by its somewhat slovenly composition in parts. A little more care on the part of those responsible for its publication in this country would have greatly enhanced its value, and would have rendered its study much easier and much more agreeable. Surely both the author and the publisher know that in this country we use the word aluminium instead of aluminum, which occurs throughout the book! On page 4 we find 4×6^6 instead of 4×10^6; on page 5 "teaches" instead of "reaches"; the abbreviation of circular mils denoted by cm. (the usual abbreviated form of centimetres), also by c.m. and at other times by cir. mils; "tables" for "cables" (p. 79), and so on. Apart from these blemishes it is a useful, practical work.

There are 12 chapters, and in seven appendixes are given the theoretical explanations of the formulæ, &c., used in the book. In the first three chapters the materials, gauges, mechanical and electrical properties of conductors, insulation, insulated cables and insulators are dealt with. The skin effect of conductors carrying an alternating current is very well explained, and some interesting notes on the conductivity of the atmosphere at high voltages are included in Chapter III.

Chapter IV. is on the determination of the size of conductors. In Chapter V. the method of calculating the size for a given stress in the span of an overhead conductor is explained. Specifications for overhead and insulated cables are contained in Chapter VI., and in the following chapter the method of testing wires and cables—copper resistance, capacity, insulation, localisation of faults—are briefly stated. The installation of underground and overhead cables is considered in Chapter VIII., which also includes useful notes on jointing. Chapters IX. to XI. inclusive deal with depreciation and deterioration, third-rail circuits and rail-bonding; and the final chapter is on inductance, reactance and capacity, and, in common with the other portions of the book, contains several very complete tables. Not only are the formulæ given for the calculation of the various quantities connected with conductors, but several numerical examples are also included. The appendixes at the end of the book explain the basis of the American, or Brown and Sharpe, wire gauge, the formulæ for skin effect and capacity, the thickness of rubber insulation on cables, the formulæ for direct and alternating current transmission lines, those for stresses in spans of aerial lines, the specifications in Chapter VI. and the tables giving the self-induction of parallel wires.

H. G. S.

Matriculation Magnetism and Electricity. By R. H. Jude and J. Satterly (London: University Tutorial Press.) Pp. vii. + 415. 4s. 6d.

The object of this work, as stated by its authors in the preface, is "to provide a sound course of elementary magnetism and electricity suitable for use in schools and colleges, containing a lucid account of the theory illustrated by a large collection of simple and instructive experiments." It must be stated that the authors appear to have succeeded to a great extent in attaining this ideal. Throughout, the experiments described are most suitable for school purposes, the apparatus is generally simple and inexpensive, and the exercises are quite equal to the attainments and requirements of the pupils for whom they are designed.

The book is divided into three parts, of which Part I. (pp. 1–90) deals with Magnetism. Part II. (pp. 91–225) Electrostatics, and Part III. (pp. 226–387) Electrodynamics. In all, 159 experiments are suggested; in some cases the theory is developed from the experiments, and in others the theory is stated and illustrated by experiments. Each chapter, of which there are 16, is followed by a summary and by exercises on the subject matter considered, and answers and suggestions as to the correct solutions of the exercises are given at the end of the book. Numerous fully worked problems are interspersed with the text, and a good appendix (pp. 388–395) deals with units, mechanical considerations, &c.

In Part I. the treatment of the magnetic field and of tubes of force deserves special mention, and the diagrams will be found of great assistance to the student. In Part II. the subject of potential—most difficult to elementary students—is very carefully and successfully treated. In most cases the potential of the conductor, as well as its charge, is considered, and thus confusion on these points is guarded against. The electric field is well described, and here again the diagrams given should be very valuable.

In Part III. Ohm's law is applied to the internal as well as to the external circuit; and the theory of the tangent galvanometer is developed. Although the authors give potential curves in connection with the seat of the E.M.F. of the cell, which do not seem to be in agreement with those of some other authorities, the subject is nevertheless well explained.

In Chapter XIII. an account of the chemical effects of the current is given, including a good description of secondary cells. Electromagnetism, telegraphic and telephonic instruments, suspended coil galvanometers and the heating effects of the current are considered in the last chapters.

Altogether the book is a distinct advance on many other similar publications, and it can be thoroughly recommended for matriculation students and others of a similar standard.

LEAKAGE REACTANCE.

BY J. REZELMAN.

Summary.—From the test results on various machines, the author deduces a method for estimating the mutual induction between the overhang coils of the different phases of a stator winding. Following this he proceeds to estimate the negative mutual induction between the overhang coils of the stator and rotor of an asynchronous motor.

Determination of the Mutual Induction between the Overhang Coils.

Experiments carried out on the rotor of a 1,250 KVA turbo-alternator have shown that the formula for the permeance:

$$\lambda_s = 0{\cdot}46 q_s \left(\log \frac{2l_s}{U_s} + A \right)$$

is applicable between fairly wide limits, in order that an approximation to the mutual induction between coils can be obtained by calculation.

This table of experimental results also shows that the coil (a), excited separately, induces the same voltage in a neighbouring coil (b), as (b) produces in (a) when traversed by the same current:

line (a) $e_a = 6{\cdot}4$ ..... $e_b = 4$
,, (b) $e_b = 5{\cdot}6$ ..... $e_a = 4$.

The coil (a) induces in the neighbouring coils
line (a) $e_a = 6{\cdot}4$; $e_b = 4$; $e_c = 2{\cdot}6$; and $e_d = 1{\cdot}6$.

The E.M.F. induced diminishes with increase of distance, *i.e.*, of the periphery U_s.

$e_b = 0{\cdot}626\, e_a$; $e_c = 0{\cdot}407\, e_a$; and $e_d = 0{\cdot}25\, e_a$.

To determine the mutual induction, we take:

line (a) $e_a = 6{\cdot}4$ ..... line (b) $e_b = 5{\cdot}6$ ..... line ($a+b$) $e_{a+b} = 19{\cdot}65$,

then the ratio $m_{a,b} = \dfrac{e_{a+b}}{e_a + e_b} = \dfrac{19{\cdot}65}{6{\cdot}4 + 5{\cdot}6} = 1{\cdot}64$,

represents the *augmentation* of the reactance of (a) and (b) produced by mutual induction.

In the same way:

$m_{b,c} = 1{\cdot}65$ and $m_{c,d} = 1{\cdot}64$;
$m_{a,c} = 1{\cdot}43$ and $m_{b,d} = 1{\cdot}43$; $m_{a,d} = 1{\cdot}34$.

Digitized by Google

It follows then that for the same U_s:

(1) $m_{a,b} = m_{b,c} = m_{c,d}$; and (2) $m_{a,c} = m_{b,d}$.

In order to determine the mutual induction between the overhang coils of the different phases, it is therefore sufficient to calculate:

(1) The reactance $x_{s\,I}$ of the end connections of phase I.
(2) " $x_{s\,II}$ " " II.
(3) " $x_{s\,I,II}$ " phases I. and II. connected in series; then the coefficient

$$m_{I,II} = \frac{x_{s\,I,II}}{x_{s\,I} + x_{s\,II}}.$$

For the permeance λ_s of one phase we have considered the three parts:

(a) λ_{sa} along a length l_{sa} and a periphery U_{sa}
(b) λ_{sb} " l_{sb} " U_{sb}
(c) λ_{sc} " l_{sc} " U_{sc}

l_s = the length of one end connection, being split up into l_{sa}, l_{sc}, and l_{sb}, l_{sc}. The permeance of the two phases in series can be determined by the same procedure; for this case the value of l_s is the same as for one phase only. The peripheries U_{sa2}, U_{sl2} and U_{sc2} are larger than for one phase owing to the number of adjacent turns being doubled.

As can be seen from Fig. 1, we can consider that l_{sc} still has the same value as for one phase only, but for the connections

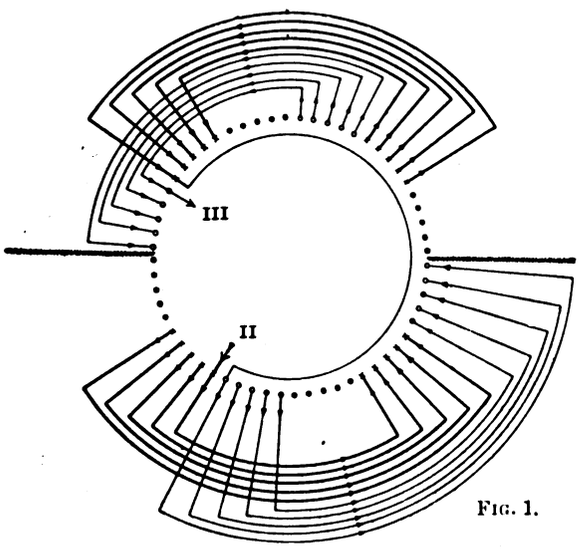

FIG. 1.

l_{sa} and l_{sb} mutual induction is only produced along a part, $C \times l_{sa}$ and $C \times l_{sb}$.

The reactance of the overhang coils in *single phase* per phase being:

$$x_{s1} + x_{sb} + x_{sc} = \frac{12{\cdot}5 \times c \times w_a^2}{p \times q_a \times 10^8} \times l_{sa} \times 0{\cdot}46 q_a \left(\log \frac{2l_s}{U_{sa}} + A\right) + \frac{12{\cdot}5 \times c \times w_b^2}{p \times q_b \times 10^8} \times l_{sb} \times 0{\cdot}46 q_b \left(\log \frac{2l_s}{U_{sb}} + A\right) + \frac{12{\cdot}5 \times c \times w_c^2}{p \times q_c \times 10^8} \times l_{sc} \times 0{\cdot}46 q_c \left(\log \frac{2l_s}{U_{sc}} + A\right)$$

$$= \frac{5{\cdot}75c}{p \times 10^8} \left\{ w_a^2 \times l_{sa} \left(\log \frac{2l_s}{U_{sa}} + A\right) + w_b^2 \times l_{sb} \left(\log \frac{2l_s}{U_{sb}} + A\right) + w_c^2 \times l_{sc} \left(\log \frac{2l_s}{U_{sc}} + A\right) \right\}.$$

That for *two phases in series* becomes:

$$x_{sa_2} + x_{sb_2} + x_{sc_2} = \frac{5{\cdot}75 \times c}{p \times 10^8} \left\{ (2w_a)^2 \times C \times l_{sa} \left(\log \frac{2l_s}{U_{sa_2}} + A\right) + (2w_b^2) \times C \times l_{sb} \left(\log \frac{2l_s}{U_{sb_2}} + A\right) + (2w_c^2) \times C \times l_{sc} \left(\log \frac{2l_s}{U_{sc_2}} + A\right) \right\}$$

$$= 4 \times \frac{5{\cdot}75 \times c}{p \times 10^8} \left\{ w_a^2 \times C \times l_{sa} \left(\log \frac{2l}{U_{sa2}} + A\right) + w_b^2 \times C \times l_{sb} \left(\log \frac{2l_s}{U_{sb_2}} + A\right) + w_c^2 \times C \times l_{sc} \left(\log \frac{2l_s}{U_{sc_2}} + A\right) \right\}.$$

The value of A is the same for the two cases; we will determine the value of C from experiments on the machines already described.

Stator of a Three-Phase Turbo-Alternator.

4,000 KVA; 4 poles – 50 ∼ – 6,600 volts between phases, 60 slots each containing 5 conductors, hence 50 turns per phase.

l_s = 1,860 mm.
l_{sa} = 1,060 mm. ..... U_{sa_2} = 620 mm. (Fig. 2)
l_{sc} = 800 mm. ..... U_{sc_2} = 1,200 mm. (Fig. 3)

The machine is wound with consequent poles, but the end connections of phase II are bent in opposite directions; the reactance of the overhang coils of phases II. and III. in series (Fig. 4) has been measured:

$$x_{sa_2} + x_{sc_2} = 1{\cdot}80w.$$

Calculation gives:

$$x_{sa_2} + x_{sc_2} = 4 \times \frac{5{\cdot}75 \times 51}{2 \times 10^8} \left\{ 50^2 \times C \times 106 \left(\log \frac{2 \times 1860}{620} + 0{\cdot}05\right) + 50^2 \times 80 \left(\log \frac{2 \times 1860}{1200} + 0{\cdot}05\right) \right\}$$

$$= 1{\cdot}29C + 0{\cdot}635; \quad A = 0{\cdot}05 \text{ from experiments,}$$

then $1{\cdot}29C + 0{\cdot}635 = 1{\cdot}8$ and $C = 0{\cdot}905$.

For this machine, the mutual induction of the end coils is high since the end connections are carried parallel with a relatively small clearance (Fig. 2); the ratio $m = 1{\cdot}55$.

B. *Stator of a Three-Phase Alternator.*

270 KVA; 14 poles – 50 ∼ – 3,000 volts between phases. 84 slots, 266 turns per phase.

The machine has a winding "per pole."

$w_a = w_b = 133$ and $w_c = 266$.

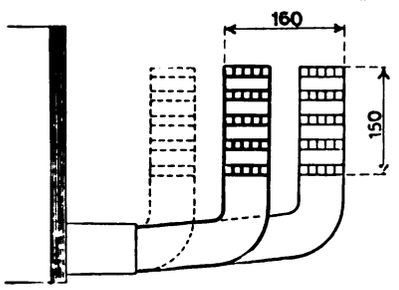

FIG. 2.

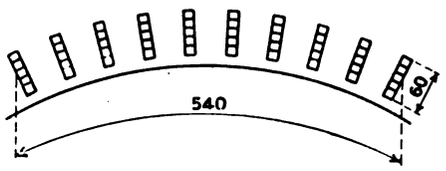

FIG. 3.

1. *Phases I. and II. in Series.*

l_s = 560 mm.
$l_{sa} = l_{sb}$ = 200 mm. ..... $U_{sa_2} = U_{sb_2}$ = 255 mm. (Fig. 4)
l_{sc} = 360 mm. ..... U_{sc_2} = 380 mm. (Fig. 5)

From experiments $A = 0{\cdot}25$ and $x_{sa_2} + x_{sb_2} + x_{sc_2} = 3{\cdot}76w$.

Calculation gives

$$x_{sa_2} + x_{sb_2} + x_{sc_2} = 4 \times \frac{5{\cdot}75 \times 50}{7 \times 10^8} \left\{ 133^2 \times C \times 20 \times \left(\log \frac{2 \times 560}{255} + 0{\cdot}25\right) \times 2 + 266^2 \times 36 \left(\log \frac{2 \times 560}{380} + 0{\cdot}25\right) \right\}$$

$$= 1{\cdot}04C + 3{\cdot}0 = 3{\cdot}76,$$

whence $C = 0{\cdot}73$ and $m = 1{\cdot}31$.

2. *Phases I. and III. in Series.*

l_s = 560 mm.
$l_{sa} = l_{sb}$ = 200 mm. ..... $U_{sa_2} = U_{sb_2}$ = 380 mm. (Fig. 4)
l_{sc} = 360 mm. ..... U_{sc_2} = 380 mm. (Fig. 5)

From experiments $x_{sa_2} + x_{sb_2} + x_{sc_2} = 3{\cdot}66w$.

In a similar manner we find $C = 0{\cdot}76$ and $m = 1{\cdot}26$.

3. *Phases II. and III. in Series.*

l_s = 560 mm.
$l_{sa} = l_{sb}$ = 200 mm. ..... $U_{sa_2} = U_{sb_2}$ = 255 mm. (Fig. 4)
l_{sc} = 360 mm. ..... U_{sc_2} = 380 mm. (Fig. 5)

From experiments $x_{sa_2} + x_{sb_2} + x_{sc_2} = 3{\cdot}96w$.

whence $C = 0{\cdot}86$ and $m = 1{\cdot}37$.

Digitized by Google

C. *Stator of a 220 h.p. Three-Phase Motor.*

2 poles; 50 ∼; 6,300 volts between phases; 30 slots with 60 conductors per slot, hence 300 turns per phase. The machine has a winding "per pole."

$w_a = 180$; $w_b = 120$; and $w_c = 300$.

1. *Phases I. and II. in Series.*

$l_s = 1{,}050$ mm.
$l_{sa} =$ 580 mm. ..... $U_{sa_2} = 500$ mm. (Fig. 6)
$l_{sb} =$ 580 mm. ..... $U_{sb_2} = 420$ mm.
$l_{sc} =$ 470 mm. ..... $U_{sc_2} = 940$ mm.

From experiments A = 0·35, and $x_{sa_2} + x_{sb_2} + x_{sc_2} = 58{\cdot}8w$.
Calculation gives:

$$x_{sa_2} + x_{sb_2} + x_{sc_2} = 4 \times \frac{5{\cdot}75 \times 50}{1 \times 10^8} \left\{ 180^2 \times C \times 58 \left(\log \frac{2 \times 1050}{500} + 0{\cdot}35 \right) + 120^2 \times C \times 58 \left(\log \frac{2 \times 1050}{420} + 0{\cdot}35 \right) + 300^2 \times 47 \left(\log \frac{2 \times 1050}{940} + 0{\cdot}35 \right) \right\}$$

$$= 30{\cdot}1C + 34{\cdot}1 = 58{\cdot}8w.$$

Whence $C = 0{\cdot}82$ and $m = 1{\cdot}31$.

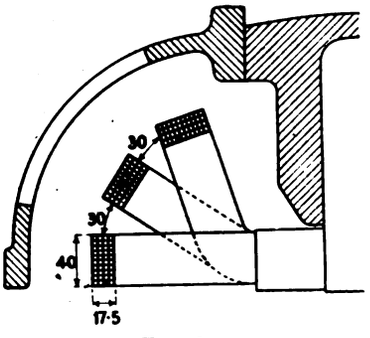

FIG. 4.

2. *Phases II. and III. in Series.*

$l_s = 1090$ mm.
$l_{sa} =$ 620 mm. ..... $U_{sa_2} = 720$ mm.
$l_{sb} =$ 620 mm. ..... $U_{sb_2} = 620$ mm.
$l_{sc} =$ 470 mm. ..... $U_{sc_2} = 940$ mm.

From experiments $x_{sa_2} + x_{sb_2} + x_{sc_2} = 61w$.

In the same way we find $C = 0{\cdot}90$ and $m = 1{\cdot}23$.
The greater distance between the coils thus diminishes the coefficient m from *1·31* to *1·23*.

3. *Phases II. and III. in Series.*

$l_s = 1{,}220$ mm.
$l_{sa} =$ 750 mm. ..... $U_{sa_2} = 500$ mm.
$l_{sb} =$ 750 mm. ..... $U_{sb_2} = 420$ mm.
$l_{sc} =$ 470 mm. ..... $U_{sc_2} = 940$ mm.

From experiments $x'_{sa_2} + x_{sb_2} + x_{sc_2} = 69{\cdot}5w$.

Whence $C = 0{\cdot}76$ and $m = 1{\cdot}26$.

These investigations have been continued on the rotor of a 175 H.P. motor, 3,000 volts, 50 ∽, 750 revs. per min., with a 2 bars per slot winding. The value of C was found to be *0·93* and m was *1·52*. For such a winding the mutual induction of the end connections is high, since the connections are carried parallel and at a small distance from each other.

To sum up

C	m	C	m
0·905	1·55	0·82	1·31
0·73	1·31	0·90	1·23
0·76	1·25	0·76	1·26
0·86	1·37	0·93	1·52

Conclusion.—With the ratio m varying from *1·25* to *1·55*, the coefficient C varies from *0·75* to *0·90*; this variation in C appears large, but when it is considered that it belongs to a term which is only a small part of the total reactance, and therefore a small error in the measurements involves a considerable change in the value of C, it is rather surprising that the variation is not greater.

It follows then, that by taking the value of C as *0·85*, we can determine with a very close approximation the coefficient of the *mutual induction* between the *overhang coils* of various phases.

Now let us see how to apply the formula in order to determine the negative mutual induction between the overhang coils of the *stator* and of the *rotor* of an asynchronous motor.

When the rotor is placed in the stator, there is a compensation of the lines of force; we will let m again represent its magnitude.

There are *three* cases to be considered:—

1. Stator *and* rotor with windings per consequent poles.
2. Stator *and* rotor with windings per pole.
3. Stator with winding per consequent poles and rotor with winding per pole, or conversely.

In the first case, the end connections are normally arranged in *two* planes, *each* phase having as many coils in *the one* plane as in *the other*. In the second case, the end coils are arranged in *three* planes, *one* plane for *each* phase.

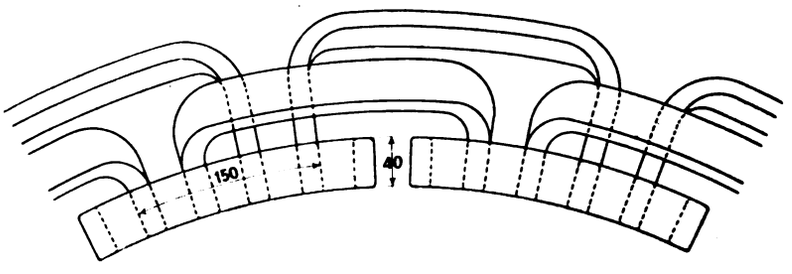

FIG. 5.

For the first case the compensation is therefore the same for *each* phase, whilst for the second it will depend on the position of the plane; it will be sufficient to consider the case of the middle plane.

The combined permeance is determined by the mean value of l_s for the end coils of the stator and the rotor, with the corresponding mean periphery U_s.

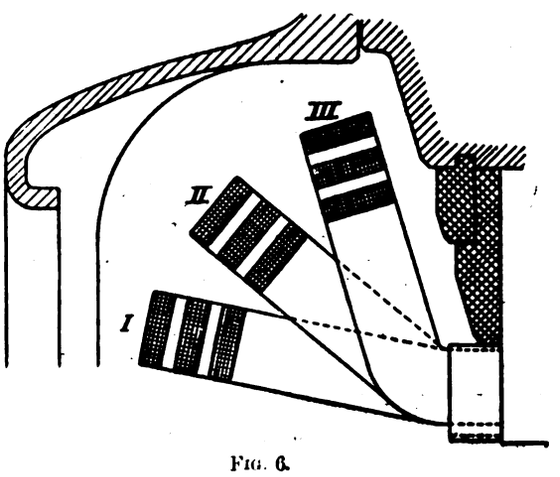

FIG. 6.

In cases 1 and 2 by calling

x_{sI} = reactance of the end coils of the stator.
x_{sII} = reactance of the end coils of the rotor reduced to the stator reactance.
$x_{sI,II}$ = reactance of the end coils of the stator and rotor, supposed connected in series and in the same sense.

Digitized by Google

Then the ratio $m = 2 - \frac{x_{s\,I,\,II}}{x_{sI} + x_{sII}}$, represents the *diminution* due to the mutual negative induction and the resulting reactance has the known value

$$2(x_{sI} + x_{sII}) - x_{s\,I,\,II} = x_{sr}.$$

In order to determine the importance of the compensation, let us consider the case of the three-phase 175 H.P. motor,

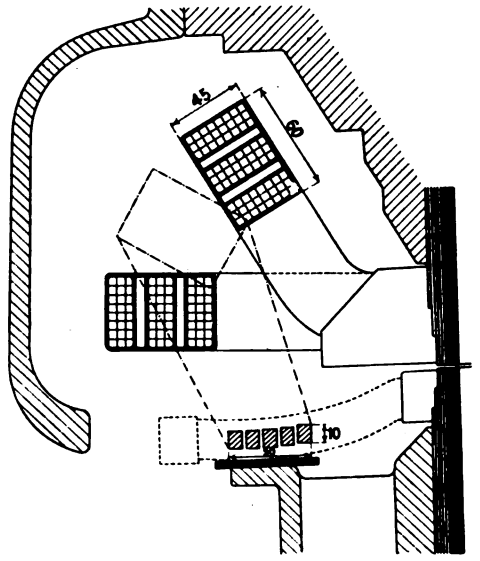

FIG. 7.

8 poles, 50 periods, 3,000 volts between phases, belonging to the third category. The stator has 72 slots each containing 23 conductors—hence 276 turns per phase—and a winding per *consequent* poles.

$l_s = 680$ mm.
$l_{sa} = 360$ mm. ..... $U_{sa} = 210$ mm. ..... $x_{sa} = 1{\cdot}865w.$
$l_{sc} = 320$ mm. ..... $U_{sc} = 250$ mm. ..... $x_{sc} = 1{\cdot}520w.$

$$x_{sI} = 3{\cdot}385w.$$

$A = +0{\cdot}06$, by experiment.

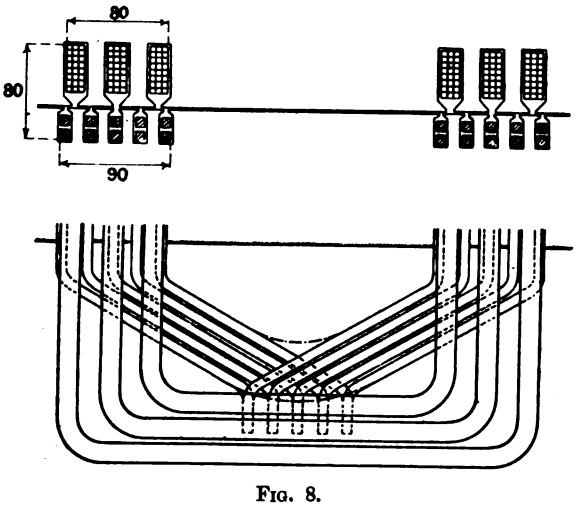

FIG. 8.

The rotor has 120 slots and two bars per slot, therefore 40 turns per phase, and a winding *per pole*.

$l_s = 420$ mm.
$l_{sa} = l_{sb} = 300$ mm.... $U_{sa} = U_{sb} = 100$ mm.... $x_{sa} + x_{sb} = 0\,0239w.$
$l_{sc} = 120$ mm.... $U_{sc} = 200$ mm.... $x_{sc} = 0{\cdot}0148w.$

$$x_{sa} + x_{sb} + x_{sc} = 0{\cdot}0387w.$$

$A = +0{\cdot}42$ from experiment.

The reactance of the end coils of one phase of the rotor, reduced in terms of the stator, thus becomes

$$x_{sII} = 0{\cdot}0387 \times \left(\frac{276}{40}\right)^2 = 1{\cdot}84w;$$

the part b does not take part in the mutual induction, reduced to the stator

$$x'_{sb} = 0{\cdot}01195\left(\frac{276}{40}\right)^2 = 0{\cdot}57w.$$

Consider now that one of the rotor phases is placed opposite to a stator phase, and also that the number of rotor turns per phase is the same as for the stator, $w_a = 276$. The winding of the stator being per consequent poles, and that of the rotor, per pole, we have

$$\begin{aligned} x_{s\,I,\,II} = {} & \frac{12{\cdot}5 \times c \times 1{\cdot}5 \times w_a^2}{p \times 10^8} \times l_{sa} \times 0{\cdot}46\left(\log \frac{2l_s}{U_{sa}} + A_I\right) \\ & + \frac{12{\cdot}5 \times c \times 3 \times \left(\frac{w_a}{2}\right)^2}{p \times 10^8} \times l_{sb} \times 0{\cdot}46\left(\log \frac{2l_s}{U_{sa}} + A_{II}\right) \\ & + \frac{12{\cdot}5 \times c \times 2 \times (w_a)^2}{p \times 10^8} \times l_{sc} \times 0{\cdot}46\left(\log \frac{2l_s}{U_{sc}} + A_I\right) \\ & + \frac{12{\cdot}5 \times c \times 2 \times w_a^2}{p \times 10^8} \times l_{sc} \times 0{\cdot}46\left(\log \frac{2l_s}{U_{sc}} + A_{II}\right) + x'_{sb} \\ = {} & \frac{5{\cdot}75 \times c \times w_a^2}{p \times 10^8}\left\{1{\cdot}5l_{sa}\left(\log \frac{2l_s}{U_{sa}} + A_I\right) + 0{\cdot}75l_{sa}\left(\log \frac{2l_s}{U_{sa}} + A_{II}\right)\right. \\ & \left. + 2l_{sc}\left(\log \frac{2l_s}{U_{sc}} + A_I\right) + 2l_{sc}\left(\log \frac{2l_s}{U_{sc}} + A_{II}\right)\right\} + x'_{sb}. \end{aligned}$$

For our motor the mean dimensions are as follows:—

$l_s = 550$ mm.
$l_{sa} = 330$ mm.; $U_{sa} = 550$ mm. (Fig. 7.)
$l_{sc} = 220$ mm.; $U_{sc} = 330$ mm. (Fig. 8.)

The estimation of the periphery U_{sa} for this motor is approximate, since the stator coils are rectangular and of wires, and the rotor winding is a bar, wave winding; however, a small mistake in this term does not have a great effect, since it acts on a logarithmic term.

We find then

$$\begin{aligned} x_{s\,I,\,II} = {} & \frac{5{\cdot}75 \times 51{\cdot}5 \times 276^2}{4 \times 10^8}\left\{1{\cdot}5 \times 33\left(\log \frac{2 \times 550}{550} + 0{\cdot}06\right)\right. \\ & + 0{\cdot}75 \times 33\left(\log \frac{2 \times 550}{550} + 0{\cdot}42\right) + 2{\cdot}22\left(\log \frac{2 \times 550}{330} + 0{\cdot}06\right) \\ & \left. + 2{\cdot}22\left(\log \frac{2 \times 550}{330} + 0{\cdot}42\right)\right\} + 0{\cdot}57 = 6{\cdot}39w. \end{aligned}$$

It follows that

$$x_{sr} = 2(x_{sI} + x_{sII}) - x_{s\,I,\,II} = 10{\cdot}45 - 6{\cdot}39 = 4{\cdot}06w.$$

and the ratio $\frac{x_{sr}}{x_{sI} + x_{sII}} = \frac{4{\cdot}06}{3{\cdot}385 + 1{\cdot}84} = 0{\cdot}775.$

For the part subjected to mutual induction the coefficient

$$m = 2 - \frac{x_{s\,I,\,II} - x'_{sb}}{x_{sI} + x_{sII} - x'_{sb}} = 2 - \frac{6{\cdot}39 - 0{\cdot}57}{5{\cdot}225 - 0{\cdot}57} = 0{\cdot}75.$$

In the cases (1) and (2) where the end connections are similar, we have:

1. $$x_{s\,I,\,II} = \frac{5{\cdot}75 \times c \times w_a^2}{p \times 10^8}\left\{4l_{sa}\left(\log \frac{2l_s}{U_{sa}} + A\right) + 4l_{sc}\left(\log \frac{2l_s}{U_{sc}} + A\right)\right\}$$

where $w_a = w_c$;

2. $$x_{s\,I,\,II} = \frac{5{\cdot}75 \times c \times w_a^2}{p \times 10^8}\left\{2l_{sa}\left(\log \frac{2l_s}{U_{sa}} + A\right) + 4l_{sc}\left(\log \frac{2l_s}{U_{sc}} + A\right)\right\}$$

where $w_a = w_b$ and $w_c = 2w_a$.

For A, the mean value for the stator and the rotor can be taken. If the rotor of the 175 H.P. motor had a winding per consequent poles, like the stator, with $A = 0{\cdot}06$ we would have

$l_s = 420$ mm.
$l_{sa} = 300$ mm.; $U_{sa} = 120$ mm.; $x_{sa} = 0\,0322w.$
$l_{sc} = 120$ mm.; $U_{sc} = 200$ mm.; $x = 0{\cdot}0097w.$

$$x_{sa} + x = 0{\cdot}0419w.$$

and reduced in terms of the stator $x_{sII} = 1{\cdot}99w.$

For the determination of $x_{s\,I,\,II}$, the dimensions would be

$l_s = 550$ mm.
$l_{sa} = 330$ mm.; $U_{sa} = 550$ mm.;
$l_{sc} = 220$ mm.; $U_{sc} = 330$ mm.; which gives

Digitized by Google

$$x_{s1,\,11}=\frac{5\cdot75\times51\cdot5\times276^2}{4\times10^8}\left\{4\times38\left(\log\frac{2\times550}{550}+0\cdot06\right)+4\times22\left(\log\frac{2\times550}{330}+0\cdot06\right)\right\}$$

$=5\cdot56w$ and $x_{sr}=2(3\cdot385+1\cdot99)-5\cdot56=5\cdot19w$.

Here the ratio $\frac{x_{sr}}{x_{s1}+x_{s11}}=m=\frac{5\cdot19}{5\cdot375}=0\cdot965$.

Suppose now the stator and the rotor to be wound per pole with A=0·42, we would have

$l_s=680$ mm.
$l_{sa}=300$ mm.; $U_{sa}=135$ mm.; $x_{sa}+x_{sb}=1\cdot20w$.
$l_{sc}=380$ mm.; $U_{sc}=250$ mm.; $x_{sc}=2\cdot48w$.

$x_{s1}=3\ 68w$.
and $x_{s11}=1\cdot84w$.

For the determination of $x_{s1,\,11}$ the dimensions would be

$l_s=550$ mm.;
$l_{sa}=300$ mm.; $U_{sa}=520$ mm.,
$l_{sc}=250$ mm.; $U_{sc}=330$ mm., which gives

$$x_{s1,\,11}=\frac{5\cdot75\times51\cdot5\times276^2}{4\times10^8}\left\{2\times30\left(\log\frac{2\times550}{520}+0\cdot42\right)+4\times25\left(\log\frac{2\times550}{330}+0\cdot42\right)\right\}$$

$=7\cdot8w$, and $x_{sr}=2(3\cdot68+1\cdot84)-7\cdot8=3\cdot24w$.

The ratio $\frac{x_{sr}}{x_{s1}+x_{s11}}=m=\frac{3\cdot24}{3\cdot52}=0\cdot59$.

Let us check finally the case of the stator wound per pole A = 0·42 with rotor wound per consequent poles and A=0·06;

$x_{s1}=3\cdot68w$
$x_{s11}=1\cdot99w$
$x_{s1}+x_{s11}=5\cdot67w$

$l_s=550$ mm.
$l_{sa}=300$ mm. ..... $U_{sa}=520$ mm.
$l_{sc}=250$ mm. ..... $U_{sc}=300$ mm.,

then
$$x_{s1,\,11}=\frac{5\cdot75\times51\cdot5\times276^2}{4\times10^8}\left\{1\cdot5\times30\left(\log\frac{2\times550}{520}+0\cdot06\right)+0\cdot75\times30\left(\log\frac{2\times550}{520}+0\cdot42\right)+2\times25\left(\log\frac{2\times550}{330}+0\cdot06\right)+2\times25\left(\log\frac{2\times550}{330}+0\cdot42\right)\right\}+0\cdot6.$$

$=6\cdot2+0\cdot6=6\cdot8_w$,

whence $x_{sr}=2\times5\cdot67-6\ 8=4\cdot54w$, and $\frac{x_{sr}}{x_{s1}+x_{s11}}=\frac{4\cdot54}{5\cdot67}=0\cdot80$.

To sum up

	$x_{s1}+x_{s11}$	x_{sr}	$\frac{x_{sr}}{x_{s1}+x_{s11}}$
1. Stator per consequent poles ($A_I=0\cdot06$) Rotor per pole ($A_{II}=0\cdot42$)	5·225	4·06	0·775
2. Stator per consequent poles ($A_I=0\cdot06$) Rotor per consequent poles ($A_{II}=0\cdot06$)	5·375	5·19	0·965
3 Stator per pole ($A_I=0\cdot42$) Rotor per pole ($A_{II}=0\cdot42$)	5·52	3·24	0·59
4. Stator per pole ($A_I=0\cdot42$) Rotor per consequent poles ($A_{II}=0\cdot06$)	5·67	4·54	0 80

The table shows that the compensation is almost negligible when stator and rotor are wound per consequent poles (where $A\simeq0$), whilst it is very important when they are both wound per pole. The compensation has an intermediate value for a mixed winding.

By calculating the value of $x_{s1}+x_{s11}$ for $A_I=A_{II}=0$ in the four cases considered it is found

1. $x_{s1}+x_{s11}=4\cdot18w$.
2. $x_{s1}+x_{s11}=4\cdot83w$.
3. $x_{s1}+x_{s11}=3\cdot635w$.
4. $x_{s1}+x_{s11}=4\ 83w$.

We can conclude from this, that with a motor of normal construction and dimensions, which we are considering, the relationship is such, that the *sum* of the reactances of the stator and the rotor and (x_{s1} and x_{s11}), calculated with $A_I=A_{II}=0$, is very nearly equal to the *resultant reactance* x_{sr}.

It follows then that the compensation by negative mutual induction is sensibly equivalent to the suppression of the induction factor A.

In addition, the positive mutual induction between phases of a winding per pole in the case of two phases in series, three-phase, will diminish, since owing to their length these common lines of force will come under the influence of the end connections of the other winding.

ELECTRICITY AND GAS IN MANCHESTER.

At the suggestion of the chairman of the Electricity Committee of the Manchester Corporation, the chief officials of the electricity and gas departments met some months ago to consider carefully the relationship existing between the two departments. Their report has now been issued, and we give below certain extracts from it.

The prices charged by each of the respective committees were considered at some length, with specific reference to the allegation that supplies were sometimes furnished below cost. We came to the conclusion that no arbitrary ruling could be laid down, as so much depended upon the conditions of supply and upon the different factors entering into each individual case. Further, we were convinced that all the prices of each department were fixed on recognised principles.

We are unanimously of the opinion that no useful purpose can be served by one department criticising the other; and that if further criticism were desirable, nothing valid could be urged as to methods of working without a prolonged special study of the problems facing each department. As the situation presents itself to us, it is simply that the City Council has entrusted to the two committees certain amounts of capital outlay, and that the City Council exacts from each committee annual sums in aid of rates. Such being the case, the question arises, on what common basis can a fair comparison be made?

The outlay on permanent works (disregarding floating stocks) should form the first line of comparison. Allowance has then to be made for the difference in the economic status of the departments. Owing to the gas department having been established many years longer than the electricity department, it has had time and opportunity to free a much larger proportion of its assets from debt than is the case with the latter department.

From a comparison of the capital expenditure of the two departments it appears that that of the gas department is £2,851,184 and of the electricity department £2,678,629. During the year the former department has contributed £46,500 and the latter £15,000 in aid of rates, *i.e.*, the percentage of rate aid to capital in the two cases is 0·67 and 0·56 of the per cent. respectively. Allowing for the probability of future gas contributions to rate aid being £50,000 (the normal figure for some years past), the gas percentage would be raised from 0·67 to 0·79, or £22,700, an excess over the electricity figure of £7,700, or 0·23 per cent. On the electricity capital this difference of percentage represents £6,160. This deficiency is explained in a supplementary report signed by the electricity officials alone.

It may be permissible to call attention to the attitude of Parliament in regard to rate aid. In dealing with certain gas bills, Parliamentary committees have laid down the condition that a maximum of only 1 per cent. on the outstanding mortgage debt should be paid over in aid of rates. In the case of the Glasgow Gas Consolidation Bill before a House of Commons commitee this year, the gas undertaking was precluded from carrying any balance of profit to the credit of the Corporation for general purposes; in fact, the committee specifically said that Glasgow ought to balance income and expenditure, and so supply at cost. It is quite clear, then, that if Manchester were now establishing its gas and electricity undertakings no option would be given by Parliament as to the extent to which profits could be devoted to rate aid. Equally clear is it that Parliament considers the benefit, if any, to accrue to the ratepayers must be calculated on the outstanding mortgage debt as being the only true measure of the ratepayers' risk.

Applying the principle laid down by Parliament to the Manchester gas and electricity undertakings, the position in regard to rate aid would be as follows:—

	Mortgage debt as at March 31, 1910.	Amount of rate aid.
Gas	£1,212,685	£12,127
Electricity	1,970,112	19,701

Digitized by Google

Leaving altogether the questions of rate aid and financial comparisons, we have considered how best to deal in the future with gas and electricity supplies for new colonies or estates where both supplies are demanded, such as has been the case at Burnage, Chorltonville, &c. As the ratepayers have a right to demand either or both supplies, provided an adequate return is assured to the Corporation on the necessary capital, it is held that the electricity department should continue exercising its powers of requiring an annual gross revenue of 20 per cent. on capital outlay on mains, and that the gas department should also demand a corresponding return. In the event of no adequate return being forthcoming for both departments from supplies to such estates, and failing a satisfactory arrangement between the departments themselves, it is suggested that such cases should be referred to a standing joint committee composed of representatives of each committee and, say, of the Finance Committee. The joint committee would not deal with all supply applications, but only with those of the nature before mentioned. A committee so constituted would necessarily consider the interests of the Corporation as a whole rather than those of either department.

In conclusion, we desire to say that we are unanimously in agreement with Parliamentary practice as to the mortgage debt being taken as the basis upon which rate aid should be computed, and the adoption of that basis by the two departments would remove all grounds for criticism in the future.

Supplementary Report by Electricity Officials.—The electricity contribution in aid of rates, after allowing for "free" capital, apparently still falls short of the gas contribution. Taking the year 1910-11, the shortage is £2,946; had the gas contribution been at the normal figure of £50,000, the deficiency would have been £6,160. As the gas contribution, judging from the experience of recent years, will probably remain at £50,000, and as the electricity contribution will at some time in the near future probably increase, the apparent shortage is in a fair way to disappear. But without waiting for that time there is already ample justification for the difference in the contribution. This will be evident when it is remembered that a sum of approximately £1,000,000 has been sunk by the Electricity Committee in meeting traction requirements, and that by arrangement between the Tramways and Electricity Committees approved by the City Council, a price of 1d. per unit is charged, representing cost only, thus precluding the earning of profit on that capital for handing over to the rates. Obviously, if the price to the Tramways Committee were increased, that committee would have its revenue reduced, and would be in a worse position for contributing to the rates. Moreover, such a step would be totally contrary to the spirit in which the Tramways and Electricity Committees and the City Council regarded the question of supply at the outset, which was that one committee should not make a profit out of the other. The validity of this has up to the present time been unquestioned.

THE PREVENTION OF ACCIDENTS IN MINES (THE FISHER SYSTEM).

As a precautionary measure against accidental shock it is usual to earth the metallic casings of motors, switches and cables in mining, colliery and industrial installations. Unless the system of earth connections is carefully made a break may occur in the earthing circuit. This, of course, has no immediate effect on the working of the plant, and a feeling of false security is engendered, whilst it may become possible for men to receive shocks, with disastrous results. The Fisher system has been introduced by Messrs. W. T. Glover & Co. with the object of removing this undoubted disadvantage from earthed systems of distribution. The Company has recently issued details of the system, and the following description applies to apparatus for three-phase circuits; modifications can, however, be introduced for direct-current working.

In connection with this system there are provided a gate end box comprising a solenoid-operated three-pole oil switch having automatic no-voltage release and overload release with variable time limit; an overload earth-circuit relay switch in series with the solenoid holding in the main switch is also included. In addition there are provided a signal lamp and shutter device to indicate whether the pressure is (1) "off" the main supply cable, (2) "on" as far as the gate end box, (3) "on" the trailing cable and right through to the motor. All these parts are enclosed in a specially cased iron box (*see* Fig. 2), which has suitable glands with armour clamp for the entry of the main three-core cable, and also a specially designed socket for the entry and inter-locking of the trailing cable plug. The trailing cable comprises a three-core rubber-insulated bitumen-sheathed cable, which can be enclosed with metallic, leather or cord protection, according to the working conditions. Beside the three main conductors there are two other conductors forming part of the subsidiary circuit, which will be referred to later. These additional conductors are laid up with the main cable, so that any damage or breakdown of the latter will interrupt the subsidiary circuit. Leakage from an incipient fault on the cable cores, if picked up by one of the subsidiary conductors, will increase the earth current in the latter, and thereby open the relay switch. Interruption of the subsidiary circuit follows, and immediately the main switch is also opened.

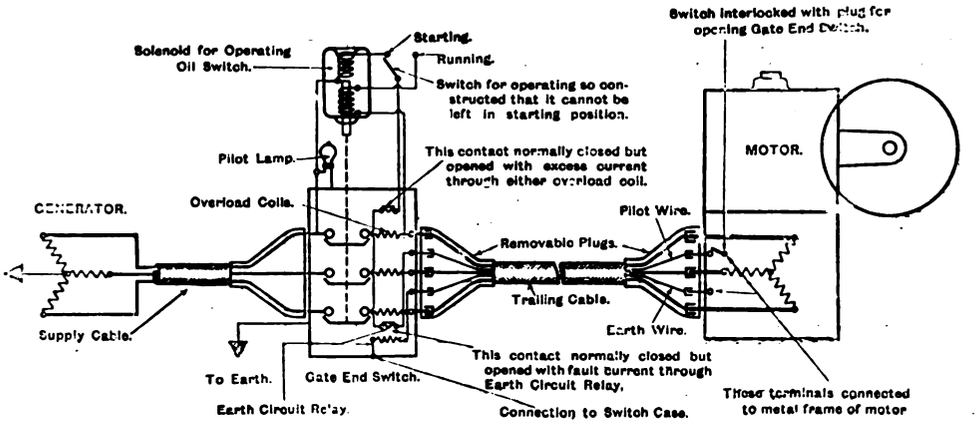

FIG. 1.—DIAGRAM OF FISHER SYSTEM APPLIED TO THREE-PHASE DISTRIBUTION.

The equipment is completed by suitable plugs for connecting the trailing cable into the gate end box and motor respectively. The gate end box plug is interlocked with the operating handle of the gate end switch, so that the plug can only be withdrawn when the switch is in the off position. Similarly, the motor plug is interlocked with the socket on the motor and the subsidiary circuit switch. This latter is used for the remote control of the gate end switch by the men at the working end of the trailing cable. The diagram Fig. 1 shows the connections between the earth wire, pilot wire and the solenoid operating the gate end switch. All these are in electrical series, and form a subsidiary circuit for the purpose of opening the gate end switch immediately upon any interruption of supply from the passage of excessive current due to faulty conditions. The scheme of connections prevents the supply being renewed until the continuity of the earthing circuit has been remade.

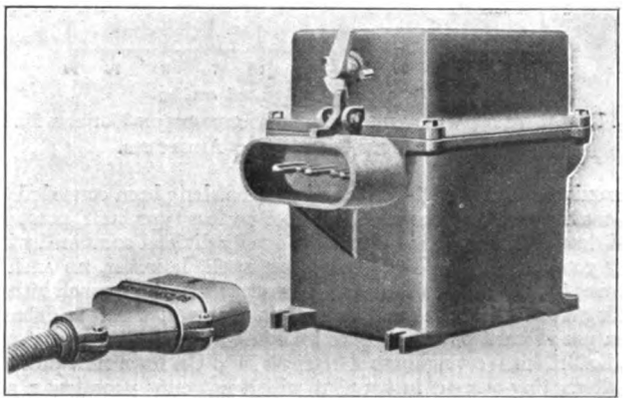

FIG. 2.—GENERAL VIEW OF FISHER APPARATUS AND CABLE PLUG.

Before current can pass from the gate end switch to the motor, both plugs, which are, of course, interlocked with the gate end switch of the remote control switch on the motor, must be inserted. When this has been done the operating handle of the gate end switch can be moved into the on position, and the subsidiary circuit is completed through the solenoid, which closes the switch in the main supply circuit. It should be noted that the operating switch is constructed on the free handle principle, so that the main circuit cannot be kept closed under fault conditions. The remote control

Digitized by Google

switch is closed by the insertion of the plug in the socket on the motor. The scheme of connections affords complete protection, in that the gate end switch is automatically tripped when any one of the following contingencies arise: (1) Accidental or intentional removal of either plug, or breakage of earth or pilot wires in the subsidiary circuit; (2) breakdown of insulation resulting in earthing or short-circuiting the main cores of the trailing cable, motor windings or other live parts in connection with them; (3) accident to the coal cutter or other apparatus, necessitating immediate interruption of the circuit; (4) constant overload, which is guarded against by the variable time limit (this admits passage of heavy starting currents, but protects the circuit against persistent overloading); (5) interruption of supply from the power house, which causes the solenoid to act as a no-volt coil; (6) leakage from an incipient fault of the subsidiary circuit operating the earth circuit relay switch.

The Fisher apparatus has the initial advantage of being portable. It also appears to meet the possible objection of colliery managers to the use of automatic apparatus in the workings. It will be gathered from the foregoing description that the whole of the protection apparatus is enclosed in a cast-iron case, and, consequently, is beyond the reach of inquisitive or vindictive workmen. The construction also provides adequately for efficient insulation, so that the apparatus is comparable with the standard appearance of the oil-insulated switchgear as now regularly used in mines.

SCALES OF ELECTRICAL INSTRUMENTS.

It is well recognised that the utility of a direct-reading instrument is closely connected with the character of the scale, crowded divisions at one end and an open scale at the other being often far from

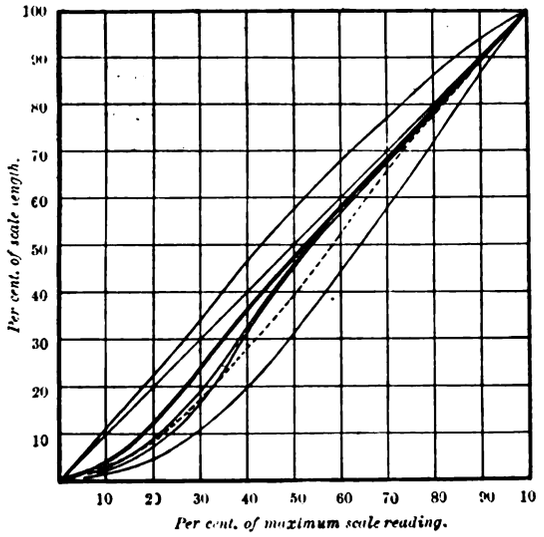

FIG. 1.—CURVE SHOWING THE SCALE DISTRIBUTION ON MODERN MOVING IRON GRAVITY CONTROLLED AMMETERS.

convenient. For direct-current work it has long been conceded that the moving coil instrument is the most perfect type built, possessing as it does a scale which is absolutely evenly divided combined with a very good accuracy. For alternating work, however, no such instrument has been available, the nearest practical approach hitherto having been the induction type of instrument, which is debarred from use in most cases owing to its comparatively heavy cost.

The British Westinghouse Electric & Mfg. Co. have now produced an alternating-current instrument which not only possesses a scale almost identical with a moving coil instrument, but which is at the same time as cheap as any instrument on the market. The type "SB," as this instrument is called, is of the well-known moving iron pattern, differing but slightly in construction from the many instruments of this class. The exceptional scale is obtained by means of a specially shaped armature, which, we understand, is the result of exhaustive experiments lasting over several months.

To illustrate clearly the improvement introduced by this scale, the makers have sent us curves showing the relation between scale length and scale reading for this and other instruments, as reproduced in Fig. 1. Obviously a perfectly evenly divided scale will have a straight line curve, and the further the curve departs from this line the more important is the division of the scale. The curve for the "SB" instrument is shown as a heavy line, and is seen to depart from the straight line much less than the other curves obtained from the scales of moving iron instruments, made by the leading makers both in England and on the Continent. Moreover, it should be observed that the Westinghouse curve is practically a straight line above 10 per cent. scale marking. A further and most interesting comparison is afforded by the dotted curve, which is that of a modern high-class induction ammeter.

When it is remembered that the instrument under consideration is suitable alike for alternating current or direct current (and this without special calibration), the cheaper cost of the moving iron instrument should cause it to be a formidable rival of the moving coil instrument. We understand that the instrument has an

WESTINGHOUSE A.C. AMMETER.

unusually light movement and a very high moving force, which, combined with first-class workmanship, should give a close accuracy and permanency of calibration. Fig. 2 illustrates one of these ammeters.

HAMPSTEAD ELECTRICAL EXHIBITION.

An interesting exhibition of domestic electrical appliances, which has been organised by the Electricity Department of the Hampstead Corporation, was opened on Tuesday last by the Mayor (Mr. Ernest Todd). This exhibition is being held at the Public Baths, Finchley-road, N.W., and will remain open until to-morrow. The exhibitors include several local contractors; for instance, Mr. E. Rivers-Smith, who is showing Ediswan and Bastian cooking and heating apparatus; the Premier Electrical Co., who are showing heating and cooking apparatus, Venetian glass shades, electrical fittings and Premelco metal filament lamps; Mr. E. G. Kellond, who is showing heating and cooking apparatus and wooden electric light fittings; Messrs. Troy & Co. who are showing Horvath "Mascot" "Metaflect" and "Solar" shop window reflector lamps; and Messrs. Roper & Co., who have a special display of the "Archer" heating and cooking apparatus. Other exhibitors, whose sphere of action is rather more than purely local, include Messrs. Siemens Bros. & Co. and Siemens Bros. Dynamo Works who are showing examples of the O.S. wiring system, as well as "Tantalum" and "Onewatt" lamps, fittings, heating and cooking apparatus and "Zed" fuses; Messrs. Purcell & Nobbs, on whose stand are fresh air electric heaters, "Electroyl" heaters, hot plates, irons and curlers; Messrs. Rashleigh Phipps, who have a special display and demonstration of heating and cooking apparatus; and the Berry Construction Co., who are showing "Tricity" cookers and cooking ranges. The Hampstead Corporation Electricity Department have an exhibition of joint boxes showing the various methods of connecting houses to the supply mains, while there is also a bureau at which full information regarding electricity supply in the district may be obtained.

Electricity Supply at Bergen.—According to "The Times Engineering Supplement," the generating station at Bergen, Norway, which contains steam-driven sets, is being replaced by a new station. This station is designed to accommodate machinery capable of developing 35,000 H.P., which is to be obtained from water-power. The work involves the blasting of a water tunnel which will exceed 2 miles in length, and which, it is expected, will take 2½ years to complete. The new station is being erected at Samnanger, to the east of Bergen, and will generate current at 7,500 volts, which will be transformed to 40,000 volts for transmission to Bergen. It is anticipated that the undertaking will be finished during 1912, and that the cost will be about £200,000.

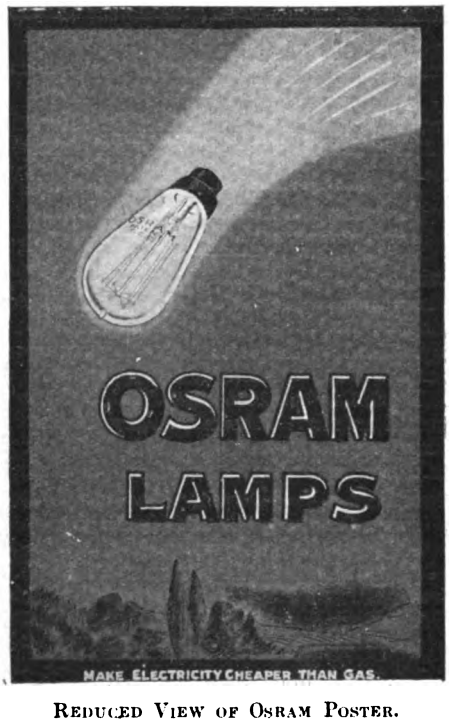
COMMERCIAL AND INDUSTRIAL NOTES.

OSRAM PUBLICITY.

The publication department of the General Electric Co. has embarked upon a vigorous campaign for assisting electrical contractors and central station engineers in making the Osram lamp even more popular than it is already. We have received a budget of Osram literature from the General Electric Co., which indicates that the advertising department has gone very carefully into the problem, and has practically covered the entire ground from the direct appeal to the public eye by large posters to the more personal solicitation of the picture postcard. Accompanying the coloured literature is a tastefully prepared booklet which generally points out the chief technical features of the Osram lamp, and also illustrates a few of the important buildings in which it is used. This particular item is worthy of acceptance by any householder, and if judiciously distributed by the electrical contractor should not fail to excite interest. At the same time, the contractor and central station engineer can affix to his letter paper tiny coloured labels which emphasise the economical properties of the Osram lamp and help to keep its merits well to the front. To that class of the public which is more technically inclined the company offers a squared paper diagram upon which a 50 c.p. Osram lamp is compared with a 65 c.p. Block Light mantle over a period of 500 hours. The cost of the two luminants is compared, and also the respective candle-powers. This is an interesting piece of literature and clearly shows how the candle-power of the Osram lamp is maintained throughout its life.



Reduced View of Osram Poster.

The Osram poster will already be familiar to our readers, as it has been displayed for some time now on the public hoardings in London and the larger provincial centres. It is an attractive multi-coloured production and should impress the name of the lamp upon the mind of the general public. A reproduction of this poster is given herewith.

A LARGE ELECTRIC CLOCK.

The Royal Liver Insurance Co. has erected enormous new offices on the Mersey side at Liverpool. The building rivals in dimensions and height the largest New York sky-scrapers, and reduces the neighbouring structures to insignificant proportions. Surmounting the building is a tower, into the four sides of which is being fitted what is claimed to be the largest electric clock in the world. Each dial measures 25 ft. in diameter, and the minute hands are 14 ft. long and 3 ft. across at the widest part. This nearly approaches the figures of the hands of Big Ben, the latter being some 16 ft. in length. Each hand is of copper with 9 in. gunmetal ribs, specially dimensioned to withstand the varying wind pressures of such an exposed position.

The dials are cast in several pieces, to facilitate manufacture, transmission and erection, and the white groundwork will be a special translucent glass only $\frac{1}{8}$ in. thick; this glass has satisfactorily stood a pressure test of 600 lb. per square inch without breaking. The hours are indicated by 12 distinctive marks instead of the usual Roman characters, and each measures 3 ft. by 1 ft. 6 in. Each of the minute marks is separated by a distance of 1 ft. 2 in. so that the actual circumference of the clock face at the minute line is 70 ft.

The clock is electrically operated on the waiting train movement system introduced by Messrs. Gent & Co., of Leicester, some years ago. The movement is such that the hands do not jump forward in half-minute impulses, but have a practically continuous motion. The waiting train movement is a reciprocating slow-speed motor

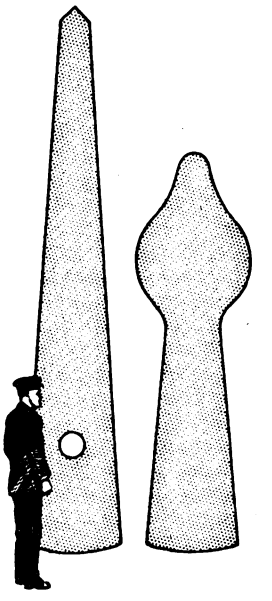


Illustration showing Comparative Size of Hands and a Man.

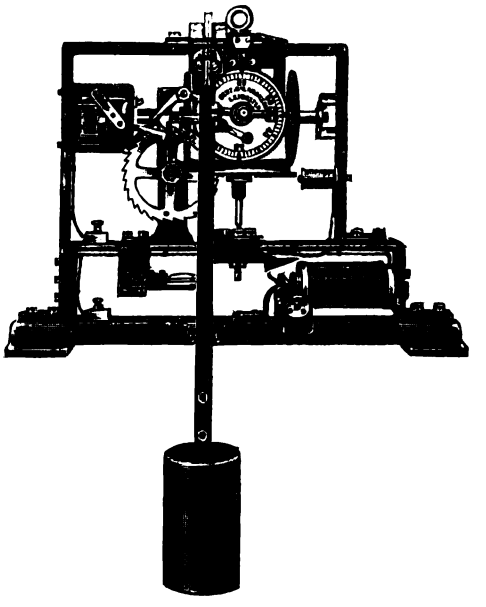


Mechanism of Electric Clock.

which rotates the hands only. The time keeping is effected by a time transmitter, which brings the waiting train movement under control every half-minute. The makers claim as a special advantage of this system that the time-keeping element of the clock is entirely independent of the hand-driving element. One of the principal features of this arrangement is that the effect of the weather cannot react on the time-keeping. The time transmitter will be connected through the G.P.O. wires to Greenwich, and will therefore automatically indicate Greenwich mean time.

The dials of this clock will be electrically illuminated, and the lamps will be lighted and extinguished by an automatically adjustable time switch. This apparatus alters the times of lighting and extinguishing to suit the seasons, and it also makes an adjustment of the error due to leap year. The accompanying illustrations give some idea of the size of the clock and also the construction of the waiting train movement.

The whole of this important work has been carried out by Messrs. Gent & Co.

O.S. WIRING.

We have referred from time to time to the O.S. wiring system and the advantages which it possesses over ordinary conduit and casing, particularly for surface work in private houses, ships, &c. We understand from Messrs. Siemens Brothers & Co. that the demand for Stannos wires, which form a portion of the O.S. wiring system, has exceeded their anticipations during the past year, and further that this demand is continuing to increase. The company is very anxious to give as wide publicity as possible to Stannos wiring, and has recently revised its catalogue and prepared a quantity of useful publicity literature. We are asked to specially call attention to the fact that the prices for Stannos wires have been considerably reduced, while the high quality of insulation and finished appearance of the covering is maintained. Stannos wires are now available in seven sizes from 1/18 to 7/16, either with ordinary or heavy sheathing. The former is employed for sizes up to 7/20, and the latter for all other sizes. The introduction of the larger sizes of Stannos makes its use possible for wiring to motors and the feeders of lighting

Digitized by Google

installations. It is now possible to carry out an "all-Stannos" job instead of a mixture of Stannos and tubing as was formerly necessary on large installations.

It will be remembered that Stannos wire, by reason of its tinned copper sheathing, can be used for concentric wiring. To facilitate this class of work a special line of continuity fixtures and other accessories, including double-wound transformers and low-voltage 1-watt lamps, have been introduced. Attention has also been paid by Messrs. Siemens to the question of cheapening the cost of house services, and for this purpose they have introduced a Stannos house service box by means of which a row of contiguous houses can be supplied. The box will take a low-tension concentric service cable up to 0·05 sq. in. and outgoing Stannos mains up to 7/16. The latter can be run along the front of the houses and branch off to smaller Stannos wires by special watertight tee-joint boxes. Included in the O.S. wiring catalogue are details of a line of Stannos fuse boards fitted with Siemens Zed fuses.

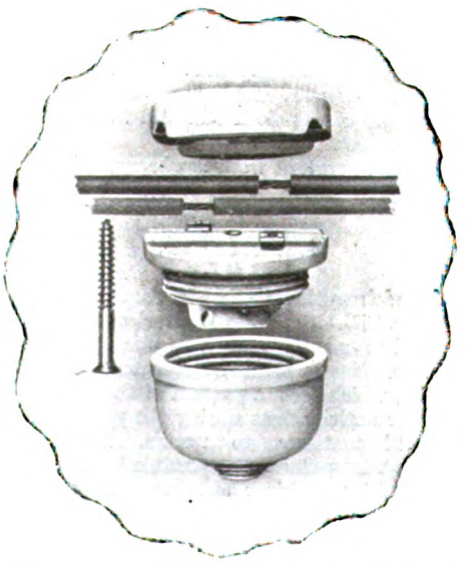
REDUCED ILLUSTRATION OF O.S. WIRING SHOW-CARD.

The catalogue has been written in a style which is readily understandable by the ordinary wiring contractor, and should assist him in introducing Stannos, more particularly to the householder.

With the idea of further exciting interest in the O.S. wiring system, Messrs. Siemens have issued a lithographed showcard, which every wiring contractor should immediately apply for and put up in a prominent position in his showroom. A reduced reproduction of this card is given herewith, and it will serve to illustrate its general suitability to the subject.

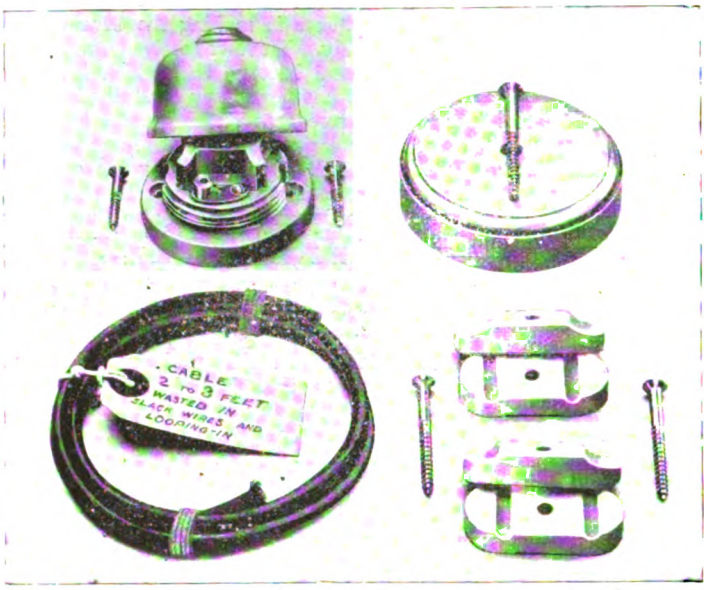
V.B. CLEAT CEILING ROSES.

Messrs. Loxley & Co., electrical engineers, Leeds, introduced about 12 months ago a type of ceiling rose which dispenses with a quantity



V.B. CEILING ROSE, ILLUSTRATING MINIMUM OF PARTS.

of the material usually employed in fixing this particular accessory for surface wiring. The ceiling rose dispenses with the necessity for the usual wood block, it does away with jointing, looping in, and straining cleats. There is no necessity to cut the wires, and the ceiling rose is held securely in position by only one screw. Similarly, there is a saving of the loops of cable which it is necessary to turn in and out of the usual ceiling rose. Not the least important item is the economy in time and labour. The difference between the V.B.



PARTS REQUIRED FOR ORDINARY CEILING ROSE, FOR SURFACE WIRING.

ceiling rose and the old pattern can best be shown by means of comparative illustrations. These are reproduced herewith and speak for themselves.

NEW TRADE LITERATURE.

House Service Cut-Outs.—A leaflet recently issued by the Edison & Swan Co. deals with an improved form of service cut-out. The base is of vitreous porcelain fixed in an asbestos lined cast-iron case. The cover is provided with a small inspection window, and all live metal parts are carefully shielded to reduce the risk of arcing to a minimum. Insulating bushes are provided, and the case can be sealed in the usual manner. A complete range of standard fuses for motor and house service work is now made in this type with 3 in., 4 in., and 6 in. break, according to the amount of current carried.

Dowsing Radiators.—The Dowsing Radiant Heat Co. directs special attention in the issue of its 1910-11 list to a considerable reduction in the price of luminous radiators. The standard of excellence in design and construction appears to be well maintained, and the revised prices should tend to materially increase the sale of these well-known radiators. Included in the list is a special description of the "solarium" or electric sun bath, which may be obtained in sizes for domestic use and also for medical institutes, hospitals, sanatoriums, hydropathic establishments, &c.

Crompton D.C. Motors.—The latest list, D.26, of Crompton enclosed d.c. motors and dynamos contains a complete specification of the machines manufactured by the company, which range in output from 2 to 125 B.H.P. The list is uniform with the company's other publications. It has been carefully compiled and the matter classified in a useful and convenient manner. The list also contains full range of prices of motors, pulleys, flywheels, foundation rig, starters and regulators.

The A.E.G., Berlin, have just issued four catalogues which respectively describe their products in the way of ironclad switchgear for medium voltages, the Tirrill system of automatic voltage regulation, a special charging switchboard for electric automobiles, and the applications of various types of meters.

Pulley-Blocks.—Messrs. Herbert Morris & Bastert (Ltd.), Loughborough, are issuing a booklet which describes fully their H.M.B. worm gear pulley-block. This is made in stock sizes to lift loads from $\frac{1}{8}$ ton to 60 tons. The block is chain-driven, and from the illustrations depicting its practical application appears to be very a useful and handy device. The booklet will be sent to interested engineers immediately on request.

Instruments.—The Walsall Electrical Co. is now issuing a list which describes and prices a line of d.c. and a.c. instruments for switchboard, testing and portable use. A noticeable item in the catalogue

Digitized by Google

is an inexpensive form of portable voltmeter and ammeter. Both of these instruments are of the moving coil type, and the latter is a central zero instrument.

Cryselco Lamps.—The story of the manufacture of the Cryselco carbon and metal lamps is well told by a hypothetical personage "Chris Elco" in a booklet entitled "Light Notes on a Light Subject." This is being issued by Cryselco Limited, Kempston Works, Bedford.

CRYSELCO WORKS. THE CONTROL ROOM.

The reading matter of the booklet is couched in terms readily understandable by the average layman, and constitutes an interesting account of electric lamp manufacture. The illustrations are accompanied by line diagrams which clearly explain the processes of

CRYSELCO WORKS. THE PUMP ROOM.

manufacture. In addition to the story of the Cryselco lamp there are numerous illustrations of the standard patterns of both metal and carbon lamps. The booklet is a creditable production and should materially assist Cryselco sales.

Protection against Short-Circuit Dangers on High-Tension Networks.—In a recent issue of the "Atti" della Associazione Elettrotecnica Italiana, Mr. Fano described the arrangement used for this purpose by the Neapolitan Supply Co., whose network includes 25 miles of cable and 37½ miles of overhead work, the supply being three phase at a pressure of 5,000 volts, and a frequency of 42. It was recognised that the most efficacious means of protection against short circuits was to connect continuously all the insulating apparatus in the station and all the insulators on the line. The neutral points of all the transformer secondaries as well as the lead covering of the cables are also connected up in the same way. When a current flows through this circuit a signal is given at the generating station or sub-station, and is immediately followed by the cutting out of the damaged section. The operation of this arrangement is based on the difference in strength between the normal and short circuit currents in the return circuit.

LEGAL INTELLIGENCE.

Eck v. Union-Castle Mail Steamship Co. (Ltd.)

An interesting case came before Judge Rentoul in the City of London Court on Thursday last week, when Mr. H. Justus Eck (of the Union Electric Co.) sought to recover £4. 12s. 2d. from the Union-Castle Mail Steamship Co., who charged him that sum for extra accommodation on their intermediate liner the "Avondale Castle."

Mr. Eck, with his wife and daughter, went to Capetown in August last year in a Union-Castle boat, travelling first class. They returned in December, paying £56 for accommodation.

The evidence was to the effect that when they had been at sea some days Mrs. and Miss Eck could not occupy their cabin any longer because of the complete absence of ventilation. Counsel for plaintiff said that the company, in one of their booklets, stated that "a complete system of ventilation had been adopted, and that electricity was brought to bear on the cabins, saloons, &c., by the adoption of a large number of electric fans." There was (counsel said) no fan in Mrs. Eck's cabin, and Mr. Eck had to pay £4. 12s. 2d. to enable her to occupy a cabin where she could have the accommodation she needed. He contended that the company had been guilty of a breach of contract and misrepresentation. The cabin without a fan was quite intolerable. The porthole of the cabin could not be kept open because of the Trade winds.

On behalf of the company it was urged that they did not guarantee that every cabin would have an electric fan in it. The case was of the greatest importance to all steamship companies, as actions might be brought against them broadcast.

Judge RENTOUL said he thought anybody reading the booklet would think the cabins had electric fans in them, and Mrs. Eck's cabin had not. If there had been a fan in her cabin, no matter how badly ventilated it was, the company would not have been liable. If fans had been provided and they had gone wrong there would have been no case. He must, in the circumstances, find for Mr. Eck, with costs.

Leave to appeal was refused.

Torquay Tramways Arbitration.

Mr Archibald Read has now given his award in the arbitration between Torquay Corporation and the Torquay Tramways Co. to decide whether the Corporation have unreasonably withheld their consent to the adoption by the company of the overhead system of traction on the Torbay-road, in lieu of the present surface contact system, and whether the Corporation have an absolute veto in the matter.

In the award (which is in the form of a special case for the opinion of the Court, owing to the contention of the Corporation that he had no jurisdiction), the arbitrator states that he disagrees with the statement of the Corporation's counsel that the Corporation's right of option as to the system to be used on the Torbay-road was given as a consideration for the Corporation's waiving its claim for a financial guarantee. The provision in sec. 61 that the consent of any local authority to the exercise of any powers shall not be unreasonably withheld appeared to apply to every case throughout the Act, and therefore to the provision in sec. 58 that the Torbay-road tramway should not, except with the consent of the Corporation, be constructed on the overhead system. The Corporation, on June 21, themselves resolved, if negotiations then proceeding proved abortive, to refer the matter to arbitration. At a preliminary meeting with the arbitrator the Corporation raised no objection as to jurisdiction. He asked the Court to state whether, if he had not jurisdiction, the Corporation had not waived their objection and were therefore now debarred from raising it. From the first the Dolter system was most unsatisfactory and expensive to work. On May 2 the Board of Trade gave notice that they would not renew their license after Oct. 31 and it therefore became necessary to adopt some other system. He found that, as a fact, if the committee's terms had been accepted they would have advised the Council to give their consent. The noise of the tramways was increased by the contact of the skates with the studs. He had come to the conclusion that there was no reasonable ground for supposing that the amenities of Torbay-road would be appreciably affected by the overhead system. The electric light would be carried on the tram poles of about the same height as the present standards. They would not obstruct the view of the bay as they would be on the land side of the road, except opposite King's-road gardens, and from the gardens the wire could not be seen by persons sitting down as they would look right over it, and the number of standards would not be greatly increased. The æsthetic objection was based more on conservative tradition and a natural initial prejuidce than on solid fact. He thought the majority of the Corporation were prepared to consent if they could get their price. He found that the "G.B." system had proved on the whole a failure and that the Lorain system would, under the prevailing conditions at Torquay, be a doubtful and costly experiment and not likely to gain the approval of the Board of Trade. Owing to the discredit attaching to all surface contact systems it would be impossible for the company to finance those systems, with the result that it must abandon its undertaking. The alternative of constructing tramways 4 and 4A on the overhead system had never, in fact, been offered to the company, and if it had it was impracticable, unreasonable and impossible, having regard to the character of the route and the fact that the capital spent on the Torbay-road would be sacrificed. There was a statutory duty to maintain the Torbay-road route. He had come to his decision without

Digitized by Google

taking into consideration the fact that the company would by a contrary decision lose £140,000 capital, although he was of opinion that some weight might properly be attached to that. He awarded that the Corporation's consent had been unreasonably withheld and that the Corporation pay the company the costs of the arbitration.

Cruse & Others v. Willans & Robinson.

At the Manchester Assize Courts on Wednesday Mr. E. Pollock, Official Referee, commenced the hearing of this action by Mr. H. Cruse (trading as the Cruse Controllable Superheater Co.) and Messrs. E. Grether & Co. against Messrs. Willans & Robinson, of Rugby, for the recovery of a sum of £10,000 for alleged breach of contract. Mr. E. M. Pollock, K.C., M.P., and Dr. Atkinson appeared for plaintiffs, and defendants were represented by Mr. J. Sankey, K.C., and Mr. Stewart.

For plaintiffs, it was stated that defendants contracted to manufacture for plaintiffs certain superheaters to the plans and specifications of plaintiffs. The plaintiffs alleged that some of the machines were not in accordance with the terms of the contract, and that in consequence they had incurred loss in replacing the superheaters. They also alleged that they had lost the benefit of other contracts.

Defendants denied that any breach of contract had been committed, and affirmed that the machines were made according to the terms of the agreement between the parties.

Mr. H. CRUSE gave evidence in support of the claim, and was under examination the whole of the day. He said he rejected the machines upon a report made to him by experts in January, 1909. As to a counter-claim in respect of undelivered superheaters, he could not possibly have erected them because he had a report that it would be dangerous to do so.

The case was adjourned.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

Littleborough Urban District Council invite applications from competent men prepared to act as clerk of works, under the direction of their consulting engineers, during the laying of h.t. and l.t. electric cables and the installation of h.t. switchgear. Salary 3 guineas per week. Applications to the clerk of the council, Mr. Geo. H. Wild, Council Offices, Littleborough, near Manchester, by Monday, Oct. 7. See an advertisement.

The Governing Body of the Northampton Polytechnic Institute invite applications for the post of laboratory demonstrator in the electrical engineering and applied physics department. Applicants should be qualified to take charge of heat, photometric and electrical engineering laboratories. Commencing salary £100 per annum. A junior demonstrator is also required. Commencing salary £80 per annum. Particulars and forms of application (which should be returned by Oct. 10) from the principal, Dr. R. Mullineux Walmsley. See an advertisement.

An assistant is wanted in the electrical test-room by the Cambridge Scientific Instrument Co. Ltd., Cambridge. See an advertisement.

A draughtsman is required, accustomed to the design of c.c. motors, dynamos and switchgear.

A mechanical engineer is required to take charge of steam plant at Shoreditch Council's electric power station, Whiston-street, London, N.E. Salary, £3 per week, rising to £4, with house, &c. Applications to Borough Electrical Engineer by noon, Oct. 12.

Mr. W. A. Turnbull, chief assistant electrical engineer at York, has been appointed resident engineer at the Stoke-upon-Trent electricity works, under Mr. C. H. Yeaman, the chief electrical engineer of the county borough of Stoke-upon-Trent, which includes the works at Burslem, Hanley, Longotn and Stoke.

Mr. L. Romero has been promoted by Salford Electricity committee to the position of mains engineer at a salary of £180 per year, rising by £10 every two years to £230.

Mr. H. F. Barnes, of Eccles, has been appointed an assistant engineer at Rawtenstall electricity works.

Mr. O. B. Richardson has resigned his appointment as engineer-in-charge at Shoreditch (London) Council's Whiston-street station, to take up the position of baths superintendent under the same Council.

Mr. T. M. Nelson, assistant engineer of Launceston (Tasmania) tramways department, has been appointed electrical engineer to Christchurch (N.Z.) Tramway Trust. Mr. Oswald Claudsley (London) succeeds Mr. Nelson at Launceston.

Mr. A. Fraser (Melbourne) has been appointed engineer of the Korumburra municipal electricity works.

Mr. Chas. A. King, A.R.C.S., of Sunderland, has been appointed assistant professor of mechanical engineering at the Heriot Watt College, Edinburgh.

Mr. H. W. Mansfield, works foreman at Woolwich electricity works, who has been on probation for six months, has had his appointment confirmed and his salary fixed at £170, with annual increments.

EDUCATIONAL NOTICES.

Armstrong College, Newcastle-on-Tyne.—The session commenced on Sept. 26. There are full courses of instruction in mechanical, marine, civil and electrical engineering, naval architecture, mining, metallurgy, agriculture, pure science, arts and letters. Particulars from the secretary, Mr. F. H. Pruen, M.A., Armstrong College, Newcastle-on-Tyne.

At the meeting of the governors on Monday Dr. R. Spence Watson was elected first president under the new constitution, and Sir Hugh Bell was elected chairman of the Council.

Finsbury Technical College.—Attention may be called to the forthcoming course of lectures on Indiarubber by Dr. P. Schidrowitz at the above college. The first of a series of six lectures will be delivered on Oct. 12 at 7:30 p.m. From the programme submitted it is clear the subject will be treated in a distinctly practical way and that the field covered is sufficiently wide to be of use to all engaged in any of the numerous industries in which indiarubber is employed.

BRITISH NOTES.

Aberdeen.—By a majority the Electricity committee have decided against the adoption of the suggestion of the city electrical engineer (Mr. J. Alex. Bell) to introduce a system of giving bonuses to employés at the electricity works in order to encourage them to practise economy in keeping down the works costs.

Acton.—By 11 votes to 9 the Council have decided to transfer their electricity undertaking to the Metropolitan Electric Supply Co. for 42 years, in consideration of the company paying off all the loan charges and paying the Council £5,000, £2,500 of which is due when a net profit of 6½ per cent. is made. Further particulars of the terms of the transfer were given in our last issue, p. 1040.

Aston.—The L.G. Board have sanctioned a loan of £12,515 for additional plant at the electricity generating station and the Alma-street sub-station, £450 for site for sub-station in Alma-street, £2,250 building and equipment at that station, £4,500 excess expenditure on mains, services, &c., up to March 31 last, and £6,000 to defray expenditure on mains from April 1 last.

Barnstaple.—The Council are endeavouring to popularise the use of electricity for lighting, power and domestic purposes, and among other steps to be taken it has been decided

To appoint a firm, or firms (not exceeding two), who will energetically undertake canvassing business, such firm to have exclusive right of supplying incandescent lamps to the Council at a rate to be agreed and to receive a rebate for current supplied to them in consideration of an effective display of electric light fittings being made. A special committee has been empowered to draw up a scale of charges and (subject to the approval of the Electric Light committee) to make such terms and arrangements as the latter committee shall approve and direct. The official appointment of a suitable firm (or firms) has been left to the Electric Light committee on the recommendation of the special committee, and any firm (or firms) so appointed to be permitted to style themselves official electrical repairers and contractors to Barnstaple Corporation.

Beaconsfield.—The Uxbridge & District Electric Supply Co. and Callender's Cable & Construction Co. have intimated to the Council that they will apply for a provisional electric lighting order.

Bermondsey (London).—The Council have entered into agreements with a number of companies and firms for the supply of electrical energy for power, including Abbot's and Yardley's wharves, Crypto Electrical Co., &c.

Bispham.—A sub-committee has been appointed to superintend the erection of the electricity generating station in Red Bank-road.

Brighton.—The Tramways committee recommend the Council to appoint a joint sub-committee (of the Tramways, Lighting and General Purposes committees) to consider the question of the price to be charged for electricity for traction, with power to determine the price to be paid by the Tramways to the lighting department during the current financial year.

The tramways track in Queen's Park-road, from Elm-grove to the Pepper Box, is to be repaired at a cost of £1,540.

Brumby and Frodingham.—At a recent meeting of ratepayers it was decided by a large majority to adopt electricity for street lighting.

Burnley.—Major Pringle inspected the new branch tramway line in Briercliffe-road last week.

Caerphilly.—The Council have accepted the offer of the South Wales Electrical Power Distribution Co. for lighting the side streets at Aber, Senghenydd and Llanbradach.

Digitized by Google

Canal Lighting.—The series of locks on the Caledonian Canal at Banavie, known as Neptune's Staircase, is now lighted electrically. Current is supplied by the Fort William Electric Light Co.

Cardiff.—Negotiations are proceeding between the Corporation and Llandaff and Dinas Powis Council as to supply of electricity by the corporation to a number of houses just outside the borough boundary in Whitchurch-road.

Central London Railway.—A start has been made with the work of extending the Central London Railway from the Bank to Liverpool-street, a distance of about 500 yards, but the loop at the Liverpool-street end will necessitate about 300 yards additional permanent way, making the total extension about half a mile.

The vertical shaft at Liverpool-street has been sunk at the West Suburban booking office, and the main operations will be conducted from that point and will proceed westward towards the Bank. From the new station near Broad-street station access will be given to the G.E. and Metropolitan Railways and (by means of lifts) to the high level platform of the L. & N.W. and North London Railways.

Dundalk.—The L.G. Board have sanctioned a loan of £20,000 for municipal electricity works. At the local inquiry strenuous opposition was offered by the local gas company.

Electric Arc Lamps and Fire Scares.—There appeared in the Halifax "Evening Courier," on the 27th ult., an instructive paragraph on the subject of

False Alarms of Fire.—The inhabitants of Greetland and Elland were last night alarmed about 10 o'clock by the fire buzzer in West Vale sounding its long and dread note of alarm. Many people hurried from home, anxiously inquiring where the fire was. This morning it was clear that there had been a false alarm, and people are now wondering whether something can be done to prevent alarms.

The Alarm heard in Halifax.— Many people in Halifax also rushed from their houses, for the ominous sounding whistle could be plainly heard all over the town. Quite a large crowd hurried from the Booth Town district. One report circulated was that a big mill at the bottom of Haley-hill was on fire.

The glare in the sky, later found to be from the new electric arc lamps that have been erected along North Bridge and up New Bank, gave credence to the story.

All this excitement was due to the new electric lamps of the Jandus regenerative flame lamp type lately erected on the bridge. The Jandus Company, perfectly naturally, we think, are amused, and write: "In case our gas friends should put this forward as another fire of electrical origin we hasten to publish the correct version. Possibly, however, the gas journals will find comfort in the thought that the sickly green of their high-pressure gas can never be mistaken for anything but gas."

Electricity in Collieries.—The Harton Coal Co. are putting down electric power and lighting plant at their Harton, Bent House, Boldon St. Hilda and Whitburn collieries, all of which are close to South Shields. The whole of the steam plant at the Harton Colliery has been superseded, and all the machinery and appliances are entirely worked by electricity. A new electrical winding engine, designed to deal with an output of 240 tons of coal per hour, has been put down.

Exhibition.—It is announced that there will be a Coronation Exhibition at Shepherd's Bush, London, next year which will be representative of the various parts of the British Empire. The exhibition authorities will devote a proportion of the receipts to the Mansion House Fund for a National Memorial to King Edward VII., and a minimum donation of £5,000 will, it is stated, be guaranteed.

Grimsby.—At a recent meeting of the Public Lighting committee the electrical engineer (Mr. W. A. Vignoles) reported that the street lamps were being converted from gas to electric lighting at the rate of 25 to 30 per week, the first 36 of the new lamps being used for the first time on Sept. 9. About 200 posts had been erected and the fittings delivered.

Hanwell.—In reference to the Metropolitan Electric Supply Co.'s contract for lighting Uxbridge-road the company suggest that instead of fixing 12 flame arc lamps (combined with small incandescent lamps) a new type of high candle-power metal filament lamp should be used which would give an improved light.

The revised proposal is to place 30 high candle-power lamps on either side of the main road, spaced on alternate tramway pillars, half the lamps to be extinguished at midnight. The company, in order to show the effect of the new lamps, are arranging to fix some experimentally.

Haslingden.—Both Haslingden and Accrington Corporations have sent deputations to the Board of Trade with reference to an objection lodged by the Lancashire Electric Power Co. to Accrington's application for powers to supply Haslingden with electricity in bulk, in accordance with an agreement arrived at between the two Corporations. The company had power to supply Haslingden, but it appears that they declined to bring a main to Haslingden alone when Rawtenstall and other neighbouring authorities decided not to take current from them.

Heston and Isleworth.—£3,048 is to be borrowed for an extension of the electricity undertaking, and application is to be made for sanction to borrow £1,200 and £800 for mains and house services respectively.

As an alternative to the existing rates for current, consumers using power continuously for not more than 12 hours daily are to be supplied at a fixed annual charge of £10 per kilowatt, payable quarterly, to be based on the maximum number of kilowatts demanded at any one time. The charge for current for cooking apparatus is 1½d. per unit.

Hornsey.—Application is to be made to the L.G. Board for sanction to borrow £2,000 for mains and £4,000 for house services.

The borough surveyor (Mr. E. J. Lovegrove) is to report on the subject of lighting the business parts of the borough.

There were 1,858 consumers of electricity on Aug. 31, an increase of 56 in two months, and the equivalent of 96,500 30-watt lamps is connected to the mains.

Application has been made to the L.G. Board for sanction to a further loan of £6,000—£2,000 for extensions and £4,000 for house services.

Hydro-Electric Works in Canada.—Work has been started on the Edmonton municipal scheme for the erection of hydro-electric works at Fort Saskatchewan. Current will be supplied for lighting and power.

Irlam.—In view of the proposal to erect new iron and steel works on the banks of the Manchester Ship Canal at Irlam, the Council are considering the question of electricity supply, and also of extending the Salford tramway system to the district.

King's Norton and Northfield.—There was a surplus of £590. 19s. 7d. on the working of the Moseley and King's Heath tramways for the year ended March 31, and of £25. 9s. 3d. on the Pershore-road tramways. The whole has been carried to the relief of the rates.

Kingsbury.—Private consumers will shortly be supplied with electric energy.

Leeds.—The Tramways and Electricity committee have decided to commence the work of equipping the City-square and Farnley route on the railless trolley system.

Lydney.—The Rural Council have modified the conditions upon which the Chepstow Electric Light & Power Co. is to supply electricity in the district. The maximum price to be charged is 6d. per unit and the company is to have 12 months' notice of the termination of the arrangement.

Municipal Wiring.—Tynemouth Corporation and Barking Urban Council have intimated that they will give financial assistance to the scheme of the Municipal Electrical Association for promoting a bill to authorise all municipal electricity undertakers to wire consumers' premises, &c. Stepney (London) Council will give their moral support and the question of financial assistance will be considered when the bill is drafted.

Mutford and Lothingland.—The District Council have decided to oppose a proposed application for a provisional electric lighting order.

Naval Electricians.—It is officially announced, in regard to the advancement of electricians in the navy to chief electricians second class, that a roster of electricians who have passed for chief electricians is to be established at each port, and candidates are to be placed on it in order of passing.

Electricians who desire to pass for chief are to be examined before requalifying in the schools. 70 per cent. of the marks in any one subject, or 75 per cent. in the aggregate, are required in order to pass. Candidates who fail to obtain the requisite percentage may, on the recommendation of the torpedo school, be allowed to present themselves for re-examination in three or six months, a second rejection being final.

Newport (Mon.).—The local ratepayers' association are threatening the Corporation with proceedings to restrain them from alleged illegal practices in connection with the electricity supply and tramways undertakings.

Northampton.—The Corporation propose to apply for powers to extend their tramway system, to employ the railless trolley system of traction, to run motor omnibuses, &c.

Oldham.—Owing to the increasing demand for electrical energy for lighting and power the borough electrical engineer (Mr. S. Wilmott Newington) has reported to the Electricity committee that further extensions of plant will have to be considered without delay.

Oswaldtwistle.—Accrington Electricity committee have agreed to supply electricity in bulk to Oswaldtwistle on terms similar to those contained in the agreement with the Haslingden Corporation.

The minimum payment is to be £200 for the first year, rising by £50 per year for seven years. The Corporation offer to promote and transfer

Digitized by Google

a provisional order for supplying and distributing electricity in Oswaldtwistle.

Otley.—Another scheme has been brought forward for supplying electrical energy in Wharfedale.

The intention is to erect a generating station at Otley with radiating mains throughout the town, and also as far as Burley and Menston, each of which is 2½ miles distant. Otley Council will be asked to give its approval of the application by a company which is about to be formed for a provisional order to enable it to supply the district with electricity.

Ottery St. Mary.—At a recent public meeting, presided over by Lord Coleridge, it was unanimously decided to form a local company for establishing electricity works in the district. Mr. L. Steele is acting as consulting engineer.

Paisley.—An arbitration, under the Paisley District Tramways Order Confirmation Act, 1901, to settle the price to be paid for the electrical energy for the next seven years to Paisley Corporation by the Paisley District Tramways Co., commences to-day (Friday), at Westminster Palace Hotel, London. The arbitrator is Mr. Robert Hammond, M.Inst.C.E., and the engineers engaged in the case are Messrs. Mordey & Dawbarn for the Corporation and Mr. H. F. Parshall for the company.

Perth.—The Council have referred back a recommendation of the Gas committee to adopt electric stoking machinery for charging the retorts at the gas works at a cost of £4,000.

Presentations.—The Chelmsford staff of Messrs. Crompton & Co. have presented a case of cutlery to Mr. H. J. Harrop on his marriage.

The staff of the North-road electricity works, Brighton, have presented a case of cutlery to Mr. Stanley Gravett on his marriage.

Public Tendering.—On the subject of public tendering and its results we have received from the Davis Electrical Co. (Ltd) a letter as follows:—

TO THE EDITOR.

SIR: We think the following facts deserve publicity. Last year we quoted the Isle of Thanet Electric Tramways & Lighting Co., of St. Peter's, Kent, for their annual supplies of general stores. By reason of the wording of the specification samples had to be inspected at the stores, St. Peter's, which necessitated a special journey there for the purpose, occupying practically a day. We were in due course notified that our tender for certain supplies had been accepted; but from that day to this we have not been favoured with a single order for the accepted portion of the tender. In response to a letter to the engineer and manager we have received no acknowledgment. As the company are inviting tenders for next year's supplies we consider the time opportune to bring this matter before the trade.—Yours, &c.,

THE DAVIS ELECTRICAL CO.

17, Moor-street, London, W., Sept. 27.

St. Helens.—Sanction has been received by the Council to a loan of £10,206 for extensions to the electricity generating plant, &c.

Salford.—An agreement has been entered into with Manchester Corporation for a temporary supply of electrical energy from Sherbourne-street sub-station during the ensuing winter months. The agreement is determinable on three months' notice from either side

South Shields.—An inquiry was held on Wednesday into the application of the Corporation for sanction to borrow £9,410 for extensions of the electricity undertaking.

Mr. PRITCHARD, who appeared for the Corporation, said the application was for sanction to borrow money for extending the generating plant in order to meet the demand for power. That demand had grown in a satisfactory and rapid manner. The undertaking had made a profit every year, with the exception of the first four and last year, when there was a loss of £206.

Opposition was offered by the North Eastern Railway Co. and Smith's Dock Co., represented by Mr. Vesey Knox, K.C., who suggested an adjournment to enable the Corporation to consider the question of taking a supply of electricity in bulk.

Mr. Pritchard offered no objection, and the inspector (Mr. E. A. Sandford Fawcett), in adjourning the inquiry *sine die*, suggested that the engineers for the respective parties might make a joint report on the matter.

Southampton.—A loop tramway line is to be laid between Northam and St. Mary's roads, and plans are being prepared for another loop.

The cost of laying the tramways to the pier will be £2,000, and if the line is extended to the West Station the additional cost will be £5,250. The general manager (Mr. H. F. Street) recommends the extension of the track to the boundary, the cost being £3,150. The committee have recommended that powers be obtained for the construction of various tramways.

Southgate.—The North Metropolitan Electric Supply Co. intend laying a trunk main from Enfield to Wood Green, passing through Southgate.

Stepney (London).—Application is to be made to L.C.C. for sanction to borrow £7,150 to cover cost of plant at Limehouse generating station.

From March 31 to Sept. 17 the number of units purchased in bulk were 3,742,129 against 3,375,490 in the corresponding period last year. The maximum load during the two periods was 122,305 equivalent 30-watt lamps in 1910 and 108,274 in 1909, the net available plant being equivalent to 74,000.

The Works committee have again considered the proposals of L.C.C. for electrification of the tramways in Burdett and Grove roads and the Council have decided not to consent to the use of overhead traction.

Stoke-on Trent.—The borough electrical engineer (Mr. C. H. Yeaman) has reported to the Electricity Supply committee as to the urgent necessity of providing additional plant at the several electricity works in the borough.

Mr. Yeaman has been instructed to prepare and obtain information as to the financial position of the electricity undertakings and report at the earliest date as to the amounts to be included in a loan for over-expenditure and prospective expenditure. He was further instructed to report as to the best means of supplying electricity in Fenton.

Teignmouth.—The surveyor and gas manager have been asked to report upon a proposal by the Electric Supply Corpn. to supply electricity in bulk to Teignmouth area, provided the Council lay the mains and distribute the electricity in their area, as the Board of Trade are threatening to revoke the order.

Tonbridge.—An inquiry was held yesterday (Thursday) into the application of the Council for sanction to borrow £1,441 for extensions of the electricity undertaking.

Village Lighting.—Mr. E. Lewis, who is supplying electricity at Glais, Llansamlet and Ystradgynlais, has offered to give a supply in Ystalyfera, Swansea.

Walsall.—An inquiry was held here last week into the application of the Council for sanction to borrow £23,225 for extensions of the electricity undertaking. Originally the Council applied for sanction to a loan of £35,000, but after inquiry the L.G. Board withheld their consent, and asked the Corporation to consider suggestions which were made by the inspector.

The TOWN CLERK stated that there was no opposition to the loan, and although some communication had been received from the Shropshire, Worcestershire & Staffordshire Electric Power Co., the latter were not represented at the inquiry. Their desire had been, if possible, to come to some arrangement with the corporation who, however, could hold out no hope that they were likely to take a supply in bulk from the company.

The inspector (Mr. Ross HOOPER) intimated that, having on a previous occasion discussed the corporation's existing system of generation and distribution of current, he was in a position to state that the department fully appreciated the difficulty the corporation were in with regard to affording a cheap supply of current for manufacturing purposes, particularly in view of the proximity of the town to Birmingham and Wolverhampton. To meet that difficulty the corporation proposed to introduce a more modern system, and although the scheme had been held over for reconsideration on certain material points, he was prepared to take it that the general principle was accepted, and that the department recognised that the corporation's present system did not afford them the elasticity of supply which they desired.

The TOWN CLERK said the Corporation had appreciated the value of the criticism which the inspector had offered at the previous inquiry. There were three points to which the L.G. Board had drawn attention. They were that, instead of building a new generating station, the existing building should be enlarged; that further consideration should be given to the question of taking a supply in bulk from a power company; and also to the wisdom of extending the area of supply to Bloxwich. The Corporation had now decided to give effect to the first suggestion, and by the removal of certain old plant they would obviate the erection of a new building. An offer had been obtained from the Shropshire Power Co. to supply current in bulk at 0·75d. per unit, subject to the corporation taking a minimum supply of 2,500,000 units per annum; but the borough electrical engineer (Mr. A. S. Barnard) had satisfied the committee that he could, with the new plant, generate current at 0·52d. per unit, and his estimate was supported by the fact that during the past six months he had kept the cost down to 0·62d. per unit. The company had in a letter addressed to the L.G. Board made a comparison with what the Corporation had done in the past, but the Corporation asked that they should be judged by what they were prepared to do in the future. Under all the circumstances, the corporation felt it to be in the interests of the whole town that they should continue to generate the current they required, particularly as a great loss would be entailed if they had to scrap their existing plant. With regard to the Bloxwich extension, the committee had the opportunity of supplying current to Messrs. Lambert Bros.' new works at the Birchills, while they hoped to gain other new customers.

Replying to the inspector, Mr. A. S. BARNARD said he was not prepared to say that the loan would meet the requirements of the undertaking for the next five years. Up to the present, however, the corporation had not been able to offer terms which would induce manufacturers to use electricity for power.

Digitized by Google

Walthamstow.—The salary of the electrical engineer (Mr. G. R. Spurr) has been increased by £50 per annum, and that of the assistant (Mr. W. H. Taylor) by £25 a year.

Additional plant is to be put down at the electricity works at a cost of £9,500

Walton.— Fifteen additional electric lamps for street lighting are to be erected by the Council at a cost of £56. Current will be supplied by the Urban Electric Supply Co., which already maintains 45 street lamps.

Warrington.—The borough electrical engineer (Mr. F. V. L. Mathias) is to report upon the provision of an automatic fire recorder at the generating station.

Wednesbury.—It was announced at the last meeting of the Council that the L.G. Board had given their sanction to loans amounting to £4,000 for extension of buildings and plant at the electricity works without the usual inquiry. The electricity undertaking had made considerable progress, and was now in a very healthy condition.

West Bromwich.—The borough electrical engineer (Mr. W. A. Jackson) has reported upon the comments made by the L.G. Board inspector (Mr. H. Ross Hooper) at the recent inquiry into the application for sanction to borrow £11,386 for a 1,000 kw. direct-current turbo-generator.

Mr. Jackson states that he has carefully considered the question of adopting alternating-current plant as suggested by the Inspector, and the results have more than justified his own support of the direct-current system. He estimated that the costs (interest, sinking fund and running charges) would be increased by nearly 50 per cent. per annum by the installation of an alternating-current turbo-generator. The direct-current supply had effectively met the demand for power in the borough up to the present, and he saw no reason to spend an additional £2,000 in putting down alternating-current plant.

West Hartlepool.—The Corporation have decided to enter into an agreement with the Seaton Carew Iron Co. by which the Corporation will be allowed to utilise the waste heat from the furnaces for the generation of electricity. A new generating station will be erected near the Seaton Carew Ironworks, and the present station will be used as a reserve. In return for the permission to use the waste heat from the furnaces, the Corporation are to enter into a special arrangement with regard to the supplying of electricity to the ironworks. The capital expenditure involved is between £17,000 and £20,000.

West Saltney.—The Parish Council are considering the question of adopting electric lighting at Queen's Ferry.

Wigan.—The L.G. Board have sanctioned the borrowing of £36,000 for the electricity undertaking, including £21,228 in respect of plant, and £8,855 in respect of mains.

The Electrical Engineer and the Waterworks Manager have been instructed to prepare plans and specifications for installing two electrically-driven centrifugal pumps at the pumping station. The electrical engineer (Mr. James Slevin) reported to the Waterworks committee that the cost of two Rees Roturbo centrifugal pumps (including motors and starters) would be £282, and two three-throw Worthington pumps (including motors and starters) £1,224. The efficiency of a three-throw pump was 8 per cent. higher than the centrifugal, and from his knowledge of the centrifugal pump combined with the difference in capital cost, he had no hesitation in recommending centrifugal pumps. With regard to annual cost, he (Mr. Slevin) was prepared to recommend his committee to supply the current necessary at an annual cost of £500.

The Tramways committee have approved an estimate of £2,700 for providing additional tramway loops.

Wimbledon.—The Watch committee are considering the adoption of a new system of fire alarms, and favour the Gamewell system, which is estimated to cost £193. 10s.

Winchester.—Mr. Archibald Read has been appointed Board of Trade arbitrator to ascertain the price to be paid by the City Council to the Winchester Electric Light & Power Co. for their electricity undertaking. The date and place of the arbitration are not yet fixed.

Wireless Telegraph Notes.—The tests that have been made for effecting reliable telegraphic communication between vessels in the air and terra firma, and vice versa, have made considerable progress during the past week. Experiments have taken place on the War Office grounds on Salisbury Plain which are reported to have proved more successful than was anticipated. Little further has to be done to bring the system into perfect working order. Mr. Barron, of the Marconi Co., is working with Mr. Thorne Baker in completing apparatus to overcome the few remaining difficulties.

On the coast of Korea a number of wireless telegraph stations are to be established, and also on the near islands of Sochong and Hangmun.

Particular care has been observed in selecting the site of a wireless station at Ceylon, and it is understood the choice has fallen upon Galle as the most eligible spot.

It is announced that Mr. Marconi, who has recently landed in Argentina, has notified Marconi's Wireless Telegraph Co., of London, that he has successfully accomplished wireless communication between Clifden (Ireland) and Buenos Aires, a distance of 6,000 miles.

Wireless on Channel Steamers.—We were last week a passenger on the "Onward," one of the South Eastern & Chatham Railway Co.'s turbine Channel steamers, which has now added to the comfort of its passengers the means of sending messages, both business and social, to either shore. This is one of the first of the S.E. & C. Co.'s boats to be furnished with these facilities. The compact station on the upper deck was the object of much attention and curiosity from the passengers, who are able to watch the work and take an interest in what is going on. In connection with these messages the railway company are acting as agents for the Post Office. The charges are as follows:—From the ship to England 3d. per word (half for the ship and half for the Post Office), minimum charge 2s. 6d.; to France, Belgium and Germany, 4½d. per word; to Switzerland, Italy and Austria, 5d. per word; to Denmark, Sweden and Norway, 5½d. per word. In all these latter cases the minimum is 3s. The wireless service promises to be very popular, and will, moreover, help to make the crossing of more interest to those who are not good sailors, or who think they are not.

Workhouse Lighting.—Canterbury Guardians have postponed for three months the question of the electric lighting of the workhouse.

Birmingham and District Electric Club.—The opening meeting of the session will be held at the Colonnade Hotel, New-street, Birmingham, on Saturday evening, Oct. 8, Mr. G. O. Donovan, M.I.E.E., in the chair. A smoking concert will follow.

COLONIAL AND FOREIGN NOTES.

American Submarine Cable Project.—It is announced in the "Review of the River Plate" that an American syndicate will shortly apply to the Uruguayan Government for a concession for a cable between Montevideo and New York.

Argentina.—The "Review of the River Plate" says the Soc. anon. Luz Electrica de Alavarria has been granted legal status, and that the Soc. anon. Alumbrado Electrico de San Antonio de Areco and the Soc. Co-operativa Luz Electrica de General Belgrano are being formed.

The electricity supply station at San Francisco (Cordoba) was recently opened.

The Cia. de Electricidad de la Provincia de Buenos Aires recently purchased the electricity works in Mar del Plata. A movement has been started in favour of the formation of a co-operative electric light company in the same town.

Mr. E. Volpatti has applied to Buenos Aires municipality on behalf of French and English capitalists for a 50 years' concession for electricity supply.

Australasia.—The "Australian Mining Standard" states that (*Gawler* (S. Australia) Council are in favour of the expenditure of £260 on plans and specifications for electricity works.

A recent meeting of ratepayers decided to adjourn consideration of the question for three months. The mayor stated at the meeting that the capital cost of the scheme would not exceed £6,600, and the annual income (at 8d. per unit) was estimated at £1,600. The present price charged for gas by the local company is 11s. per thousand.

A recent report of the directors of the *Balmain* (N.S.W.) Electric Light & Power Supply Corpn. states that an agreement has been entered into for the supply of electricity in Newtown for 57 years from January next, and the directors have decided to issue debentures for £25,000 to pay for this extension, and also to hire out motors.

The report on the *Sydney* municipal electricity undertaking for the year ended June last states that the output of the Ultimo power house was 56,462,781 units (42,529,719 a.c. and 13,933,062 c.c.), an increase of 19·63 per cent. over the previous year. The erection of the second of the two 5,000 kw. turbo-alternators ordered from England in May, 1907, has been completed, and the 12 additional boilers were almost ready. The new city sub-station has been equipped with three 1,500 kw. rotary converters, and a 1,000 ampere-hour battery booster and a 1,000 ampere-hour battery has also been installed at Dowling-street car shed. A contract was placed in June for an additional 5,000 kw. turbo-alternator, to be supplied early next year.

Mr. F. A. Hermann is preparing to submit (on behalf of the Foos Electric Supply Co., of America) a scheme for electricity supply in *Kapunda* (S. Australia).

The *Kilmore* (Victoria) Electric Supply Co.'s accounts show a debit balance of £403, but numerous additional applications for current are in hand.

Mansfield (Victoria) Progress Association recently decided to obtain expert advice as to electricity supply.

Australian Postal Telegraph Service.—The Royal Commission on the Australian Postal Telegraph services have issued their report, and among other recommendations are the appointment of a board

Digitized by Google

of management to administer the department and the nationalisation of the cable services connected with the Commonwealth.

Austria-Hungary.—It is stated that the communal authorities of Podgorze (near Cracow) have earmarked (amongst other sums) £8,300 for extensions of the City electricity works.

Brazil.—The Government have approved plans for the electrification of the Victoria-Diamantina railway to Itabira do Matto Dentro.

The Ministry of Communications have been authorised to spend £25,500 on the construction of a telegraph line between the States of Matto Grosso and Amagonas.

Acting Consul-General Hambloch (Rio de Janeiro) writes that attention was called in his report for 1908 to the fact that Germany had increased her percentage of machinery, &c. import trade every year, while imports from the U.K. were declining. In 1909 the share of the U.K. in the imports of machinery, &c., increased by 2½ per cent., the value of her trade in 1909 showing an increase of more than 12 per cent. over that of 1908, chiefly due to increased imports of locomotives and electrical apparatus. Germany's share in the trade in machinery, &c., was lower in 1909 than in any year since 1903.

British Columbia.—The extensions of the British Columbia Electric Railway system were opened on Monday by the provincial Premier, the Hon. R. McBride. The company has now over 80 miles of track open for traffic.

China.—In the "National Review" of China, Mr. Stafford Ransome states that the engineering imports into China in 1908 were valued at £7,192,000.

The approximate proportions of the principal countries concerned were: British Empire, 43 per cent.; United States, 22; Japan, 13; Germany and Belgium, each 8, but, according to Mr. Ransome, the British share ought to be at least 70 per cent. The increase of Japanese business with China, as far as engineering items are concerned, has been mainly at the expense of Germany. Japan is now supplying to China a great many of the cheaper products that were formerly supplied by Germany, such as electrical accessories, telegraph plant, scientific instruments, hardware, &c.; although China's total imports dropped heavily in 1908, the engineering items increased by 5 per cent. Of the imports of metals the British share was 54 per cent., United States 22, Japan 10, Belgium 7 and Germany 5. In machinery, the British share was just over 50 per cent., that of Germany 19, United States and Belgium each 10 and Japan 5. In electrical plant the British share was 44 per cent., Germany 18, Japan 17, Belgium 12 and United States 6. In railway plant, the British share was 18 per cent., United States 45, Japan 18, Belgium 12 and Germany 6. In hardware, the British share was 33 per cent., Japan 30, Germany and United States each 10 and Belgium 2. In telegraph material, the British imports were 16 per cent., Japan 33, Germany 5, United States 2½ and Belgium 1.

Exhibition.—An International Exhibition of Novelties and Patents of the Iron and Engineering Industry will be held at Budapest in May and June next. Applications for space will be received at the Ausstellungsbureau, Gyar-Uteza, 38, Budapest, until Nov. 30.

Fochabers.—The Duke of Richmond some time back established hydro-electric works for the supply of electricity for lighting and power at Gordon Castle and also for public lighting in the village of Fochabers. Owing to interference with the water supply in winter by ice, &c., it has been decided to put down a steam-driven set as stand-by plant.

The contract has again been placed with Messrs. Drake & Gorham, who were the engineers for the original installation. The plant will include a 120 H.P. engine and 75 kw. shunt-wound dynamo. Steam will be provided by a locomotive type multi-tubular boiler suitable for a working pressure of 140 lb., and fed by a duplex steam pump. A switchboard will be fixed in the new engine room, cables being carried from that point to the existing switchboard and balancers in the turbine house. The work will be completed by the end of next month.

India.—"Indian Engineering" says the Government have authorised the telegraph department to carry out the installation and repair of electrical plant in the premises occupied by the department, thereby relaxing the rule that all works in connection with electrical installations in Government buildings shall be carried out by the Public Works Department.

It is understood that the remainder of the passenger coaches of the Bengal & N.W. Railway are to be fitted for electric lighting. At December last about 800 vehicles on this railway were fitted with the Stone system of electric lighting, leaving 465 not fitted. No carriages on this line are fitted with gas.

The Rohilkund & Kumaon Railway had, up to December last, 136 out of 217 vehicles fitted with the Stone system.

The "Indian and Eastern Engineer" states that, in regard to the first section of the scheme (of which Tata & Co. are the promoters) for the generation of electrical energy by water-power on the Ghats below Lonauli, and its transmission to Bombay, an Indian company is to be registered in Bombay with a capital of 170 lakhs (about £1,134,000) to finance the scheme, and the Lahmeyer Electrical Co. have entered into a contract to supply the first portion of the plant, which is to have a capacity of 40,000 H.P..

Italy.—The Soc. Anon. delle Tramvie e Ferrovie Elettriche di Roma have obtained a concession for construction and working an electric tramway from Rome to Albano, via delle Cave, 12 miles in length.

The Soc. pei Tramways di Livorno has purchased the steam tramway from Pisa to Marina. The line is to be converted to electric traction and extended from Marina to Leghorn.

Japan.—Consul-General R. de B. Layard, in his report for 1909 of the Kobe district, says imports of machinery decreased by 46 per cent., or over £670,000 (from £1,469,004 in 1908 to £796,682 in 1909.)

In the imports of electrical machinery the proportion of British to German and American goods has increased greatly. British electrical machinery is much esteemed by the Japanese, but cheapness is likely to outweigh quality. In machinery of other kinds there has been a great diminution of imports, due principally to the general depression in business throughout the country. Many new electric light and tramway companies were started during 1909, to which cause the increase in the imports of electrical machinery is to be attributed, but the boom came to an end with the close of the year. Cheap machine tools are now being turned out in ever increasing quantities by Japanese engineers which presumably satisfy requirements, although the foreign importer is of the opinion that they are unsatisfactory. There are now many small cable manufacturing concerns working in Japan; only one of these concerns, however, competes in quality with the imported goods, and this one is equipped with British machinery and has the services of a British expert.

The British Vice-Consul at Osaka says that the manufacture of machinery of all kinds is extensively carried on in Osaka. There is a growing demand for motors of various kinds owing to the great increase in the use of power in the smaller factories. With the exception of the spinning and weaving industries, by far the greater part of the machinery used in the Osaka factories is of Japanese manufacture, the designs having been taken from foreign models. In this connection, the importance of taking out patents in Japan for any new machinery imported into the country cannot be too strongly impressed upon British manufacturers. Since the commencement of the year numerous schemes have been brought forward for electric tramways to various places in the neighbourhood of Osaka, including one to Nara (a town of about 45,000 inhabitants situated 25 miles east of Osaka), another to Kyoto on the opposite side of the Government railway to the line just completed, a line for an express tramway service between Osaka and Kobe, and many others. The only one, however, for which a charter has been obtained is a line to Sakai, 6 miles to the south of Osaka. This will run parallel to the Nankai railway to Wakayama, which has already been electrified as far as Hamadera (4 miles beyond Sakai), and is shortly to be electrified for the rest of its whole length of 40 miles. The other tramway schemes, however, are hardly likely to mature for several years.

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough or constant use, price 8s. 6d. post free. A complete Index is included.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Edinburgh.—The accounts of the electric lighting department for the year ended May 15 states that capital expenditure is £1,031,833 (increase £22,669).

Capital borrowed is £1,029,278, of which £343,520 has been repaid. Revenue was £127,103, working and general expenses were £58,502, the surplus carried to net revenue account being £68,601. After adding £806 proceeds of reserve fund above prescribed limit, and providing for interest £19,611, contribution towards liquidation of debt £40,404 and income tax £1,995, the surplus for the year is £7,397. Units generated were 17,848,940 (compared with 17,636,385 in previous year), and 1,833,222 (1,806,946) were supplied to street arc lamps, 30,725 (25,691) to street incandescent and stair lamps, 9,580,909 (9,833,301) for public lighting, and 3,864,637 (3,589,527) for motive power.

Glasgow.—The Corporation tramways earned "record" traffic receipts last week, the amount being £19,874. 9s. 11d., compared with £17,902. 0s. 11d. in the corresponding week last year. The miles of double track open are 97¾, compared with 94½. The best week previously (ending Oct. 5, 1907) was £19,689.

A Citizens' committee has been formed to oppose the principle of rate relief from the tramway surplus.

Digitized by Google

Marylebone (London).—The general manager of the electricity undertaking (Mr. A. H. Seabrook) reports that the gross income for the June quarter shows an advance of £160 over the corresponding three months of 1909. Eliminating the adjustment item (which applies to accounts prior to June) the real increase is £419.

The increase in units sold to private consumers number 113,447 or 6·2 per cent., compared with 8 per cent. estimated for the whole year. The total increase in units sold (including public lighting) is 260,577, or 14 per cent. The average price during the quarter, including meter rents, was 3·103d. per unit, and in June, 1909, 3·240d., a drop of 4·2 per cent. In the previous June the decrease was 11·5., and the estimate for this year was 9 per cent. Generation expenses were £4,173, against £4,888 and £4,930 in 1909 and 1908 respectively. The total expenditure during the three periods was £10,578, £10,048 and £11,785. There was an increase in each of the headings except generation. As to management and distribution expenses (£2,017 and £2,220, against £1,717 and £2,081), the increase was mainly due to the larger establishment necessary to cope with the increased activities of the department and the additional consumers on the books. They had added double the number of new consumers compared with the preceding year (600 against 300), and although the value of revenue per consumer was smaller, the establishment charges were nearly as heavy. The cost of production was 1·20d. per unit, against 1·29d. in 1909, and 1·54d. in 1908.

With regard to the sales department the income included £2,360 sundry sales, which, less prime cost (£1,805), left a balance of £555. The rental of motors on hire amounted to £100, maintenance of consumers installations £101, and payments under hire purchase agreements £98, total £856. Expenditure was £1,365, leaving net debit balance £509. Various orders in hand were incomplete, but taking credit for these on a conservative basis the net debit on the sales department was £368. After taking all things into consideration the probable actual cost of this department for the quarter did not exceed £273, which was the ascertained cost of the old publicity department during June quarter, 1909. The net result of the quarter's trading was a credit balance of £15,485 compared with £15,188 in the previous June quarter.

Melbourne (Australia).—The accounts of the municipal electricity department for the year ended Feb. 28 show capital expenditure £575,291 (increase £19,043).

Revenue was £113,579 (compared with £102,636 in the previous year). Working and general expenses were £54,662 (£52,458), leaving £58,917 (£52,458) gross profit. Capital charges were £42,188 (including £19,612 for depreciation and renewals), leaving a balance of £16,808, out of which £2,922 was applied to recouping the capital account for cost of changing over installations, £4,000 allocated as a special appropriation for depreciation and renewals, and £7,000 contributed to general town fund. Motors connected increased from 1,218 to 1,441 (4,684 H.P.), increase 1,115 H.P. There are 3,212 consumers (increase 359), of whom 1,178 take supplies for power and heating. 9,790,435 units were generated (compared with 8,642,154 in previous year), 3,654,063 (3,380,162) supplied to private consumers for lighting and 2,560,991 (1,911,355) for power and heating, 1,694,370 (1,574,137) for street lighting and 250,539 (226,613) for municipal buildings. There are 972 arc and 4,163 incandescent lamps in use in streets and Corporation buildings, and 79,717 yds. of feeders, distributors, street lighting cables and pilot wires laid for c.c. supply and 39,930 yds. of 4,000-volt feeders and public arc lamp cable on the a.c. system. Coal cost per unit was 0·484d. (0·532d.), total works costs were 1·003d. (1·036d.), total supply costs (including establishment and special charges) 1·003d. (1·036d.) and total costs (with attendance, renewal, &c., of public and private lamps) 1·607d. (1·698d.). Sinking fund and depreciation required 0·718d. (0·809d.) and interest 0·502d. (0·553d.)

The report of the Electric Supply committee states that a contract has been entered into for the supply of a 1,500 kw. generating set (by W. H. Allen, Son & Co.) at £9,881. A d.c. feeder to the corner of Russell and Collins-streets has been supplied by W. T. Henley's Co., at £3,695, and a feeder to supply current to the Victoria Rolling Mills, &c., by British Insulated & Helsby Cables, at £697.

Shoreditch (London).—The accounts of the electricity supply and refuse destructor undertaking for the year to March last show capital expenditure £365,656 (increase £3,477). The amount borrowed is £362,767, and £45,757 has been repaid.

Revenue for the year was £49,065, and working and general expenses were £25,189, gross profit being £23,876. Interest and provision for repayment of loans required £17,444, leaving £6,432 to carry to appropriation account. Of this amount, £4,000 was placed to reserve, £1,487 to change of pressure account and £617 carried forward, 6,900,031 units were generated (compared with 6,080,248 in previous year), 770,839 (775,997) were supplied to public lamps, 136,197 (181,983) by contract and 4,649,156 (3,915,431) by meter. There are 322 (322) public lamps. The total maximum supply demanded was 3,510 kw. (2,874 kw.). Receipts of the refuse destructor department were £9,943, including £1,336 for electricity generated, £1,181 for steam for Hoxton baths and public library, £1,318 for destruction of trade refuse and Bethnal Green and Islington refuse and £5,997 borne by general rate (£4,601 for destruction of 29,449 tons of refuse and £1,396 loan charges).

The accounts have been adopted by the Council, subject to audit.

Scuthwark (London).—Gross profit on the electricity undertaking for the year ended March 31 was £6,198. 11s. 5d., and after paying interest and sinking fund, &c., the net profit was £790.

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1910 Edition of the Big Blue Book is READY, price 15s., **post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 16th.**

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1910 Big Blue Book, making it the most complete work of the kind ever published.

TENDERS INVITED.

The Directors of the GT. WESTERN RAILWAY CO. invite tenders for one year's supply of various stores, including electrical wires and cables, telegraph ironwork and tools, telegraph drysalteries, telegraph apparatus (insulators, &c.), electric light carbons, india-rubber goods, glass, acids, alkalies, &c., oils and turpentine, zinc, antimony, brass, copper rivets, &c., wire, fishplates, bolts and nuts for permanent way, &c. Samples and patterns may be seen at the general stores, Swindon, from Oct. 10 to 15. Specification, with forms of tender, from the Stores Superintendent at Swindon. Tenders, addressed to the secretary, Mr. A. E. Bolter, Paddington Station, London, W., by Tuesday, Oct. 18. See also an advertisement.

Tenders are invited (until Nov. 22) for supply of telephone cable (schedule No. 337) and (until Nov. 29) for testing instruments (schedule No. 338) to the Postmaster-General's Department in VICTORIA. Tenders, forms, &c., from the Commonwealth Office, 72, Victoria-street, London, E.C. See also an advertisement.

Tenders are invited by Nov. 23 for supply of cable ironwork, c.i. pipes, earthenware conduits, switchboards, telegraph and telephone instruments, &c., to the Postmaster-General's Department in QUEENSLAND. Tender forms and specifications from the Commonwealth Offices, 72, Victoria-street, London, S.W. See also an advertisement.

Tenders are invited up to Nov. 2, for supply of insulators, wire (covered, phosphor-bronze and g.i. stranded) to the Postmaster-General's Department in QUEENSLAND. Tender form and specification from the Commonwealth Offices, London, S.W.

Tenders are invited by EDINBURGH Corporation for three steam turbines and d.c. generators, each of 1,200 kw., and condensing plant and interior parts of cooling towers, for their Dewar-place electricity station. Forms of tender, &c., from Mr. F. A. Newington, Dewar-place, Edinburgh. Tenders to the Town Clerk by Oct. 10.

HALIFAX Tramways and Electricity committee want tenders (by noon Oct. 17) for supply of a 1,500 kw. turbo-alternator, with condenser, two 750 kw. rotary converters, with transformers, switchboard, &c. Forms of tender from Borough Electrical Engineer.

LONDON County Council require tenders by 11 a.m. Oct. 11, for the road work and platelaying required for the reconstruction of the Highgate-road tramways for the conduit system, and for paving works of street widenings. Specifications from the Chief Engineer.

LONDON County Council want tenders by 11 a.m. Oct. 12 for wiring and fitting Sherington-road school, Greenwich, for electric light. Specifications from the Chief Engineer.

YORK Electricity committee want tenders by Oct. 7 for 12 months' supply of carbons, carbon brushes, carbon filament lamps, meters and time switches, motors, &c. Forms of tender, &c., from the City Electrical Engineer.

CHESTER-LE-STREET Rural Council invite tenders for an electric lighting and power installation at their infectious diseases hospital

Digitized by Google

and for the erection of about 600 yds. of overhead single-phase transmission line. Tenders to clerk by Oct. 19.

HACKNEY (London) Council require tenders by 7 p.m. Oct. 13 for supply of 90,000 pairs of white open-type arc lamp carbons. Specifications, &c., from the Town Clerk.

WEST HAM Guardians want tenders by 10 a.m. Oct. 13. for electric lighting at the receiving homes, Wanstead. Specification, &c., from Mr. Wm. Jacques, A.R.I.B.A., 2, Fen-court, London, E.C.

EPSOM Council want tenders by noon Oct. 15 for supply of 1,000 tons of coal (Nixon's Navigation) to the electricity department.

Tenders are invited (till 2:30 p.m., Wednesday, Nov. 2) for supply to the Postmaster-General's department, New South Wales, of 1,000 25 c.p. metal filament lamps, with bayonet cap fittings, for 110 volts d.c. Tender forms, &c., at the Commonwealth offices, London, S.W.

The Deputy Postmaster-General, MELBOURNE, will receive tenders until 3 p.m. Oct. 18 for supply of 23 miles of telephone cable (specification 284) and 500 composition insulators (specification 374) and until 3 p.m. Oct. 25 for 10,000 Cordeau insulators (schedule 373). Specifications, &c., from 72, Victoria-street, London, S.W. Local representation is necessary.

The Deputy Postmaster-General, MELBOURNE, wants tenders by 3 p.m. Oct. 25 for supply of electric lighting material (schedule No. 311). Specification, &c., from the High Commissioner.

Tenders will be received at the office of the Deputy Postmaster-General, MELBOURNE, until 3 p.m. Nov. 8 for 500,000 jointing sleeves.

Tenders will be received by the Minister of Telegraphs, G.P.O., WELLINGTON, N.Z., up to noon Dec. 15, 1910, for supply and erection of installations of wireless telegraphy at or near Doubtless Bay, Gisborne, Cape Farewell, Sumner (near Christchurch) and Bluff. Specification, conditions, &c., at the office of the Superintendent of Electric Lines, G.P.O., Wellington, and the office of the High Commissioner, 13, Victoria-street, London, S.W. Tenders must state the name of the country in which the apparatus, &c., will be manufactured.

JOHANNESBURG Council require tenders by noon Nov. 4 for supply of five electric tramcars. Specification, &c., may be seen at 73, Basinghall-street, London, E.C.

Tenders will be received at the Ministere des Colonies, rue Oudinot, 27, Paris, until Oct. 14 for the supply and laying of a submarine cable between LIBREVILLE and LOANGO (French Congo). Deposit of £2,000 required with all tenders, to be increased to £4,000 with successful tender.

Tenders are wanted by noon Oct. 31 for supply and erection of machinery, &c., for electricity supply and water supply systems for the town of BENI-SOUEF (Egypt). Particulars may be obtained from Mr. A. L. Webb, C.M.G., Queen Anne's-chambers, London, S.W. Local representation is necessary.

The Turkish Ministry of Commerce and Public Works want tenders by Oct. 28 (Nov. 10) for a concession for the construction and working of electric tramways in CONSTANTINOPLE and suburbs. A deposit of £13,500 (sterling) is required with each tender. Local representation is essential. Copy of specification (in French) may be seen at 73, Basinghall-street, London, E.C.

TENDERS RECEIVED AND ACCEPTED.

Grimsby Public Lighting committee have placed a contract with Cryselco (Ltd.) for lamps for street lighting (with guaranteed life of 1,000 hours) at £15 per gross. The tender of Accumulator Industries (Ltd.) was originally accepted, but was, we understand, withdrawn.

Woolwich (London) Council have accepted the tender of Wilkin & Son (at £19. 17s. 6d.) for alterations to wiring, &c., at the new Plumstead vapour baths, and that of Willans & Robinson for six sets of valve lines for two engines at £41. 2s. net.

London County Council have accepted the tender of Pinchin, Johnson & Co. for supply of insulating varnishes for the tramways department.

Marylebone Council have placed an order with S. Williams & Co. (at £85) for a coal-grab for the generating station.

It is stated that a tender submitted by Wisby & Co. for the construction of electric tramways at Santa Fé (Argentina) will probably be accepted.

Bermondsey (London) Council have accepted the tender (at £20. 18s.) of the A.E.G. Electric Co. for a 5 B.H.P. motor for driving a lathe.

Chelmsford Council have accepted the tender of the Electric Supply Corporation for public lighting in the north and south ward (with arc and incandescent lamps) at £1,396. 10s. per annum.

Salford Council have accepted the tender at £145. 10s. of J. P. Hall & Sons for a compound vertical steam feed pump.

Derby Council have accepted the tender of the Union Electric Co. for 50,000 carbons at 45 per cent. discount off list price.

An order has been placed by Eccles Council with Browett, Lindley & Co. for spare parts for the 150 kw. traction set at £40. 17s. 6d.

Whitehaven Education committee have accepted the tender of D. Burns for wiring Irish-street schools.

Margate Education committee have accepted the tender of Coles Bros. for wiring the New Cross schools at £32.

Dublin Corporation have accepted the tender of the Greenmount Oil Co. for machinery oil for the electricity department.

Belfast Harbour Commissioners have accepted the tender of Siemens Bros. Dynamo Works for supply of 22 flame arc lamps.

Blackpool Council have accepted the tender of the Brush Electrical Engineering Co. for a new 40 H.P. motor for the refuse destructor.

Octavius Steel & Iron Co. are wiring and fitting the new Canning College, Lucknow, for the U.P. Government, and outside illumination and other work at the Allahabad Exhibition buildings. Osram lamps are being used for the Lucknow College.

Sydney (N.S.W.) City Council have now accepted the tenders of W. T. Henley's Co. for 36,000 zinc cable suspenders, at £216; Noyes Bros., 15 miles of 11,000-volt cable, £5,317. 8s. 3d. (delivery within 13 weeks); Ferranti Limited, section A switchgear and transformers (10,000-volt), £2,592. 16s. 11d.; and Australian General Electric Co., section B switchgear and transformers, £232.

Commonwealth Tenders.—The following tenders have been accepted by the Australian Commonwealth Postmaster-General's Department:—

Victoria: W. T. Henley's Co., lead-covered paper-insulated telegraph cable; Western Electric Co., twisted pair outside distributing wire; British Insulated & Helsby Cables, multiple magneto switchboard; Lawrence & Hanson, Leclanché porous pots; Davies, Shephard & Co., brass fittings and clips for cables and copper washers for cable boxes; Victoria Iron Rolling Co., w.i. clamps for attaching base plates to railway and tramway rails, ironwork for poles, &c.; and A. Challingworth, stayrods.

W. Australia: Leslie & Co., zincs for gravity cells.

Queensland: British Insulated & Helsby Cables, twin jumper wire; International Electric Co., triple jumper wire; Western Electric Co., lead-covered silk and cotton-insulated cable, six sections of common battery switchboard, &c.; Standard Cable Mfg. Co. and Geo. Cradock & Co., tinned copper wire, v.i.r. insulated, taped and braided.

BUSINESS NOTICES.

We are informed that the Brockie-Pell Arc Lamp Co., and Foster Arc Lamp Co. are amalgamating, and will henceforth be known as the Foster Engineering Co. (Ltd.) All existing contracts will be duly completed.

The Adnil Electric Co. have appointed Messrs. Scattergood & Johnson, of Leeds, their representatives for the sale (in the Yorkshire district) of Bergmann dynamos and motors. Mr. J. B. Chambers, who has represented the Adnil Co. in Yorkshire, having resigned, to take up an appointment in Eastern Europe.

The Lahmeyer Electrical Co. are opening offices at 2, New China Bazaar-street, Calcutta, with Mr. H. R. Speyer as their chief engineer in India.

Owing to the great increase in their business the Sloan Eletrical Co. have found it necessary to secure more commodious premises at Conradty House, 12, Golden-lane, E.C., whence they will remove shortly.

Horatio Stead and Wm. Hy. Illingworth, dealers in electrical fittings, &c., Haugh Shaw Works, Halifax, have dissolved partnership. Debts by Mr. Stead.

Hal Williams and Walter Bridges, consulting engineers, 3, Salter's Hall-court, London, E.C., have dissolved partnership.

John Norton Griffiths and Thos. Bruce Marriott (trading as Norton Griffiths, Bruce Marriott & Co.), consulting engineers, 59A, London-wall, London, E.C., have dissolved partnership.

Joseph Hodgson Woodhead and Harry Woodhead (trading as Woodhead Partners), electrical engineers and contractors, Cascoigne-street, Leeds, have dissolved partnership.

Sales by Auction.—Messrs. Marler & Marler will sell by auction at Messrs. Crisps' premises, Seven Sister's-road, London, N., on Wednesday, Oct. 19 at noon, in lots, the complete installation of electric generating plant comprising a Marshall 30 H.P. engine and boiler with steam feed heater and Allen, Weston and Paterson and Cooper dynamos, belts and shafting, arc and other lamps, &c. Catalogues of the auctioneers, 176, Sloane-street, Belgravia, London, S.W. See also an advertisement.

Digitized by Google

Messrs. Horne & Co., 35, Old Queen-street, Westminster, S.W., will sell by public auction at the Royal Arsenal, Woolwich, on Thursday, 20th inst., at 11 a.m., unserviceable and obsolete stores, including quantities of iron and steel, brass, copper, gunmetal, lead and antimony alloy, zinc, lead, aluminium, &c., tools and lifting jacks, telegraph and electric light fittings and instruments, 650 electric lamps, 43,450 electric lamp bases, &c. The lots may be viewed at the Royal Arsenal, Woolwich, on Monday, Tuesday, and Wednesday, previous to and on morning of sale. Catalogues from the War Office, Whitehall; the Ordnance Office, Tower; and the Ordnance Office, Royal Arsenal, Woolwich. See also an advertisement.

Patents Development.—The proprietor of patent No. 21,181/1905, for "Improvements relating to electrical measuring instruments," desires to enter into arrangements, by licence or otherwise, for exploiting same in this country. Applications to Messrs. Haseltine, Lake & Co., 7 and 8, Southampton-buildings, Chancery-lane, London, W.C.

The owners of patents No. 23,501/1899, relating to "Improvements in vacuum table lighting," and No. 12,582/1902, relating to an "Improved system of electric lighting," desire to negotiate with electrical engineers with the view of granting licences. Information from Messrs. Lloyd Wise & Co., 46, Lincoln's Inn Fields, London, W.C.

BANKRUPTCIES, LIQUIDATIONS, &c.

A receiving order has been made against W. H. Hunter, electrician, &c., High-street, Towyn, Merionethshire.

A first and final dividend of 1s. is payable at 24, Friar-lane, Leicester, to creditors of Alan McAlpin (trading as McAlpin & Co.), electrical engineer, 44, Cauk-street, Leicester, and Cumbergate, Peterborough.

A first and final dividend of 4½d. will be payable at the O.R.'s City-chambers, Lowgate, Hull, to creditors of Harold Bristow, electrician, &c., 368, Hessle-road, Hull.

The Cascade (1906) Power Co. (Ltd.) is being wound up voluntarily. Claims by Nov. 1 to Mr. A. G. Bartholomew, 695, Salisbury-House, London, E.C., where a meeting of creditors will be held on Oct. 14.

In the report of the official receiver in regard to the liquidation of the Mid-Oxfordshire Gas Light & Coke Co. (Ltd.) it is stated that On June 24, 1909, the company purchased the Chipping Norton & District Electric Lighting undertaking for £10,500, which was satisfied by the issue of £7,000 special debentures carrying a first charge on the undertaking and ranking with the debenture stock in regard to any deficiency, and by the issue of fully-paid preference shares for the balance (£3,500). No agreement has been filed with the registrar of joint stock companies in respect to these fully-paid shares. The electric lighting works were purchased in order to obviate competition. The company's engineer (Mr. A. F. Painter) recommended the purchase at £10,500. In May last the court, on the application of special debenture holders, appointed W. A. Slade, 9, Old Jewry Chambers, E.C., receiver and manager of the Chipping Norton Gas Works, and on May 12, 1910, he was also appointed by the court receiver and manager of the Chipping Norton electric lighting works and of the Bicester gas works. The trustees for the special debenture holders had also entered into possession of the Woodstock works. On May 19 the company resolved to wind up voluntarily, and appointed H. A. Stevens, 6, Dowgate-hill, E.C., liquidator. The failure of the company is attributed by the directors to the inability to obtain statutory powers and shortness of working capital. In the opinion of the official receiver it is also due to over-capitalisation. Mr. R. W. Thornton, C.A., Oxford, has been appointed liquidator.

Deed of Assignment.—A dividend is to be paid under a deed of assignment executed on March 18, 1910, by Ellen Derbyshire (trading as P. Derbyshire), electrical engineer, &c., 6, Duke-street, St. Helens. Claims by Oct. 10 to Mr. P. S. Booth, 35, Exchange-chambers, 2, Bixteth-street, Liverpool, or Mr. R. Else, Victoria Works, St. Helen's.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

*Note.—The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked * are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. Names within parentheses are those of communicators of inventions. When complete Specification accompanies application, an asterisk is affixed.*

SPECIFICATIONS PUBLISHED.

1909 Specifications.

13,728 Schuer. Arc lamps. (Post-dated 13/12/09.)
15,380 Simms. & Simms Magneto Co. High-tension magneto-electric machines. (Post-dated 3/1/10.)
16,332 Johnson & Billington. Electricity meters.
18,675 Medway & Scott. Switchgear for the remote control of electric motors.
18,756 Turquand & Turquand. Electric battery lamps.
19,090 Murphy. Rectifying electric currents.
19,387 Mount & Beck Flame Lamp. Arc lamps.
19,660 Farrand. Coin-freed apparatus for supplying or measuring a current of electricity.
21,179 Barbour. Homopolar generators and motors and other electrical machines having a large number of collector rings.
21,343 Kirwan & Quaney. Switches for breaking electrical circuits.
23,226 B.T.-H. Co. (G.E. Co., U.S.) Fluid meters.
23,227, 23,228 & 23,229 Murray. Electric cut-outs. (Dates applied for, 17/10/08 9/11/08, 30/11/08.)
23,291 Siemens Bros. Dynamo Works. (Siemens Schuckerwerke Ges.) Prevention of brush sparking in rotary electric frequency transformers having commutators.
23,328 Lake (Electric Press Bulletin Co.) Telegraph transmitting and receiving apparatus.
23,351 B.T.-H. Co. (G.E. Co., U.S.) Refractory insulating materials.
23,455 Dessauer. Taking photographs with Rontgen rays.
23,747 Graham. Electric signalling means.
23,802 Rogers. Audible electric signalling devices and the like.
24,017 B.T.-H. Co. (G.E. Co., U.S.) Signal systems for railways and the like.
24,109 Carrigan. Switches.
24,269 Siemens Bros. Dynamo Works, Ltd. (Siemens-Schuckertwerke Ges.) Driving and operation of electric frequency transformers having commutators.
24,302 Evans-Jackson. (Hiorth.) Electric induction furnaces.
25,383 Redfern (Compagnie Generale d'Electricite.) Soldering the filaments of incandescence lamps.
25,536 Siemens Bros. & Co. & Dieselhorst. Insulator for high-tension electric circuits.
25,719 Hosgood. Electric plug and socket couplings or connectors.
26,088 Kirwan & Quaney. Switching devices. (Post-dated 11/5/10.)
26,250 Siemens Bros. & Co. & Dieselhorst. Inductance coils for submarine and other electric cables.
26,259 Siemens & Halske Akt.-Ges. Telephone exchanges. (Date applied for 14/11/08.)
26,779 Leon & Lewis. Telephone transmitters.
27,208 Benjamin. Supporting devices for electric incandescent lamps.
27,458 Siemens Bros. & Co. (Siemens & Halske Akt.-Ges.) Automatic telephone exchanges.
27,674 Peterson. Method of charging electric resistance furnaces. (Date applied for, 7/1/09.)
27,976 De Laminiere & Soc. Anon. des Accumulateurs de Laminiere. Accumulator plates. (Date applied for, 8/12/08.)
28,429 Wynne. Switch with lever motion and instantaneous make and break.
28,555 McBride. Arc lamp.
29,068 Hirst & Angold. Arc lamps.
29,090 Siemens Bros. Dynamo Works. (Siemens Schuckertwerke Ges.) Working of single-phase commutator dynamo-electric machines.
29,240 Hubbell. Storage batteries.
30,208 Fynn. Alternate-current motors.
30,331 Stevens (Ltd.), Stevens & Lambert. Brush-holders employed in electrical apparatus.

1910 Specifications.

672 Mulacek & Hatlanek. Electrical induction smelting furnaces. (Date applied for, 1/3/09.)
349 Krause. Metal filament lamps having filament carriers arranged elastically. (Date applied for, 5/7/09. Originally included in 22,458/09.)
439 Down & Down. Electric light bracket.
467 Siemens Bros. & Co. & Riber. Telephone apparatus.

3,981 B.T.-H. Co. (G.E. Co., U.S.) Treatment of metals of the chromium group.
4,697 White & Carichoff. Control of electrically-operated switches. (Date applied for, 27.2.09.)
5,376 Fairburn-Hart (Electric Renovator Mfg. Co.) Centrifugal fans. (Date applied for 28.10.09.)
5,835 Neudorffer. Insulating wall-boxes for electric apparatus.
5,571 Midgley & Vandervell. Electric switches.
5,801 Adams Mfg. Co. (Cutler Hammer Mfg. Co.) Electro-magnetically actuated electric switches.
5,985 Smith, Green & Glover. Alternating-current induction motors.
6,160 and 6,363 Adams Mfg. Co. (Cutler Hammer Mfg. Co.) Switches.
6,667 B.T.-H. Co. & D'Arcy. Electric energy meters. (Date applied for, 20.9.09. Request under S.c. 19 of the Act not granted.)
6,658 Salzer. Supports for the filaments of incandescent electric lamps. (Date applied for, 19.3.09.)
6,668 B.T.-H Co. & Wedmore. Protective devices for electrical transmission and distribution systems. (Date applied for, 18.10.09.)
6,867 Adams Mfg. Co. (Cutler Hammer Mfg. Co.) Electric motor-controllers.
6,964 Siemens & Halske Akt.-Ges. Connections for semi-automatic telephone exchanges. (Date applied for, 20.3.09.)
7,154 Siemens Bros. & Co. (Siemens & Halske Akt.-Ges.) Electrical signalling apparatus.
7,266 Siemens Bros. Dynamo Works & Lydall. (Siemens Schuckertwerke Ges.) Single-phase commutator motors. (Addition to 2,303 08.)
7,292 Siemens Bros. Dynamo Works. (Siemens-Schuckertwerke Ges.) Electric frequency converters.
7,322 Reineking. Short-circuit detectors.
7,821 Siemens Bros. Dynamo Works. (Siemens Schuckertwerke Ges.) Arc lamps.
7,822 Siemens Bros. Dynamo Works (Siemens Schuckertwerke Ges.) Starting of polyphase electric asynchronous motors.
8,024 Graham. Telephonic transmitters.
8,141 Kathura. Duplex systems of electric telegraphy. (Date applied for, 6.4.09.)
8,409 Siemens Bros. Dynamo Works & Parker. Ventilation of continuous-current dynamo-electric machines.
8,411 Siemens-Schuckertwerke Ges. Electric searchlights. (Date applied for, 8.4.09. Addition to 12,556 08.)
8,831 Jellinek & De Tovaros. Suspension of electric trolley wires. (Date applied for, 19.7.09.)
9,045 Siemens Bros. Dynamo Works (Siemens Schuckert-Werke Ges.) Polyphase electric compensated series motors.
9,094 Politz. Protecting tubes and vessels from galvanic or electric currents. (Date applied for, 22.4.09.)
9,176 Newlands & Parkinson. Making electrolyte for primary batteries. (Application for patent of addition to 11,926 09.)
10,312 Laurent. Indicating or alarm governors for motors. (Date applied for, 11.2.10. Addition to 16,802 09.)
10,423 Lundberg, Lundberg & Lundberg. Switches.
10,577 Graham. Telephone systems.
10,705 Brown, Gatenby, Gourlay & Gourlay. Electric conduit threaders.
10,771 Adams Mfg. Co. (Cutler Hammer Mfg. Co.) Electric circuit-breakers.
10,817 & 11,155 Fessenden. Wireless signalling. (Dates applied for, 19.7.09 and 29.1.10.)
10,820 Zahringer. Operating magneto-electric ignition machines.
10,843 Morse. Power transmission mechanism. (Date applied for, 15.12.08. Originally included in 28,923 09.)
10,961 Partington. Multiple fusible cut-out for electrical circuits.
11,251 Siemens Bros. & Co. (Siemens & Halske Akt.-Ges.) Telephone exchange circuits.
11,333 Howard & Coad. Telephone mouth-pieces.
11,903 Fessenden. Variable electric transformers. (Date applied for, 18.5.09.)
12,425 Gebrueder Siemens & Co. Protective coating for bodies consisting of carbon. (Date applied for, 24.5.09.)
13,502 Akt.-Ges. Brown, Boveri & Cie. Driving of dynamo-electric machinery. (Date applied for, 22.5.09.)
13,828 Lange. Portable electric lamps. (Date applied for, 28.2.10.)
14,153 Siemens Bros. Dynamo Works. (Siemens-Schuckertwerke Ges.) Preventing permanent magnetism in dynamo-electric machines.
14,315 Attis. (Noyes.) Magneto-generators.
14,353 Siemens Bros. Dynamo Works. (Siemens-Schuckertwerke Ges.) Obtaining a braking action in polyphase commutator electric motors.
15,977 Lewis. Electrodes for arc lamps. (Date applied for, 10.3.09.)

BOOKS RECEIVED.

(Copies of the undermentioned works can be had from *The Electrician* office, post free, on receipt of published price, adding 3d. for books published under 2s., and 5 per cent. for books published nett. Add 10 per cent. for abroad or for foreign books.)

NEW COMPANIES, MORTGAGES AND CHARGES.

NEW COMPANIES.

ALLIANCE ELECTRICAL STORES (LTD.) (111,884.)—Reg. Sept. 26, capital £25,000 in 47,500 preferred ordinary shares of 10s. each and 1,250 deferred ordinary shares of £1 each, to take over the business of electricians, electrical engineers, &c., carried on by the Alliance Electrical Co. (Ltd.) (in liquidation). First directors, T. Ions (chairman), J. E. Coles and W. R. N. Grimley.

LLANGEFNI ELECTRIC LIGHT & POWER CO. (LTD.) (111,909.)—Reg. Sept. 27, capital £3,000 in £1 shares (2,750 5 per cent. cumulative preference and 250 ordinary), to carry on business indicated by title. First directors, Major L. Williams, J. Jones, W. Owen, E. J. Owen and L. Milne. Reg. office, 66, Victoria-street, London, S.W.

LYNESS SYND. (LTD.) (111,896.)—Reg. Sept. 26, capital £3,500 in £1 shares (2,000 deferred), to acquire, develop and turn to account the Lyness patent electric control finger and tip, &c. Private company. R. C. Lyness is first permanent director.

PROGRESSIVE ENGINEERING CO. (LTD.) (111,880.)—Reg. Sept. 24, capital £500 in £1 shares, to carry on the business of electrical, mechanical, motor, aerial, civil and general engineers, &c. Private company. First directors, W. Smith and A. H. Jelly.

TELEPHONE SUBSCRIBERS' PROTECTION ASSOC. (LTD.) (7,660)—Reg. in Edinburgh, Sept. 26, to combine telephone users and to protect their interests. Reg. office, 144, St. Vincent-street, Glasgow.

UNITED SHERARDIZING (LTD.) (111,901.)—Reg. Sept. 26, capital £60,000 in £1 shares (14,000 5 per cent. preferred ordinary), to carry on the business of galvanisers, zinc workers, steel and iron workers, smelters, manufacturers and blenders of alloys, metal workers, &c., to acquire the right to use the process known as "Sherardizing" or any process for covering iron, steel or other metals with a coating of zinc or other metallic substances, to acquire certain patents and to adopt an agreement with T. H. Nelson. First directors, R. F. Hanbury, T. H. Nelson, P. Dawson, Major M. F. MacTaggart and H. M. Delacour.

MORTGAGES AND CHARGES.

ELECTRO-MECHANICAL BRAKE CO. (LTD.)—A memorandum of satisfaction in full on Aug. 13, 1910, of charge dated April 27, 1909, securing £250, has been filed.

MAWDSLEY'S (LTD.)—Issue on Sept. 12 of £100 debentures, part of a series created April 26, 1909, to secure £2,000, charged on the company's property, present and future, including uncalled capital. Holder, J. H. St. Hill Mawdsley. Previously issued of same series, £1,200.

CITY NOTES.

MEMORANDA (Sept. 29).—**Bank rate 4 per cent.** (Sept. 29, 1910) **Price of silver,** 24⅛d. per oz. Consols 79¾—80¼ for money; 80¼—80⅜ **account. Consols Pay Day, Nov. 4; Stock and Shares Continuation Days,** Oct. 12 and 26; **Ticket Days,** Oct. 13 and 27; **Pay Days,** Oct. 14 and 28; **Mining Shares Carry Over Days,** Oct. 11 and 25.

Prices of Metals (London).—*Copper*, **cash,** 56¼; **three months,** 57⅛. *Lead*, **English,** 13½—13¾; **foreign,** 12¾—13. *Spelter*, 23⅝—23¾. *Tin*, **English,** 158—160; **foreign cash,** 162; **three months,** 159¼. *Iron*, **Cleveland, cash,** 49/3¼, **three months,** 49/10½.

ANGLO-AMERICAN TELEGRAPH CO. (LTD.)—The directors have resolved, after placing £5,000 to renewal fund, to declare an interim dividend for the quarter ended Sept. 30 of 15s. per cent. on the ordinary stock, and £1. 10s. per cent. on the preferred stock (less tax) payable Nov. 1.

CALCUTTA TRAMWAYS CO. (LTD.)—The directors have declared an interim dividend of 2s. 6d. per share.

CLEVELAND & DURHAM COUNTY ELECTRIC POWER CO. (LTD.)—The directors' report for the year ended June 30 states that capital expenditure on new works during the year was £8,811. The continuous trade depression had retarded the amount of new business secured. The gross profit was £12,942, against £2,098 for the previous year. After providing for interest there was a net profit of £2,906, which deducted from debit balance brought forward, leaves a debit of £751 to be carried forward.

EASTERN TELEGRAPH CO. (LTD.)—This company announce the payment by warrants on Nov. 1 of interest for the half-year ending Oct. 31 on their 4 per cent. mortgage debenture stock. The transfer books of the debenture stock will be closed from 27th to 31st inst. inclusive.

EASTERN & SOUTH AFRICAN TELEGRAPH CO. (LTD.)—This company announce the payment by warrants on Nov. 1 of interest for the half-year ending 31st inst. on their 4 per cent. Mauritius subsidy debentures. The transfer books will be closed from 27th to 31st inst. inclusive.

RIO DE JANEIRO TRAMWAY, LIGHT & POWER CO. (LTD.)—The directors have declared a quarterly dividend of 1¼ per cent.

SUBMARINE CABLES TRUST.—The coupon due on the 15th inst. will be paid by Messrs. Glyn, Mills & Co., 67, Lombard-street, E.C.
